About the Author

Patrick Li is the cofounder of AppFusions and now works as a senior engineer there. AppFusions is one of the leading Atlassian experts, specializing in integration solutions with many enterprise applications and platforms, including IBM Connections, Jive, Google Apps, Box, SugarCRM, and more. He has worked in the Atlassian ecosystem for over 9 years, developing products and solutions for the Atlassian platform and providing expert consulting services.

He has authored numerous books and video courses covering JIRA 4 to 7, including JIRA Agile and JIRA Service Desk. He has extensive experience in designing and deploying Atlassian solutions from the ground up and customizing existing deployments for clients across verticals such as healthcare, software engineering, financial services, and government agencies.

You can check out his LinkedIn profile at <https://www.linkedin.com/in/patrickliangli> or visit his company website at <https://www.appfusions.com/display/Dashboard/Bringing+it+together%2C+NOW>.

About the Reviewer

Miroslav Kralik is a product owner and Atlassian Tools Evangelist at MSD IT Global Innovation Center, and he cofounded Podporuj.cz.

His passion is to help customers succeed and make products, services, and processes better and innovative. His focus is now on DevOps and the integration of different tools in the whole development chain, where JIRA as an issue-and bug-tracking system belongs.

Besides this, Miroslav has dedicated his time to the [Podporuj.cz](#) project, which was created to support non-profit organizations in the Czech Republic and people with irreversible physical disabilities who depend on others to take care of their basic needs. Thanks to this project, it is now possible for people around the world to freely contribute with their daily activities—shopping--to the campaigns and running of NGOs.

Miroslav can be found on LinkedIn at <https://www.linkedin.com/in/mikralik>.

With this opportunity, I would like to thank all the DevOps Stack team members for their time, effort, and passion, and for the opportunity of being part of such a great team, to whom this book is also dedicated.

- On demand and accessible via a web browser

Preface

Over the years, JIRA has grown from a simple bug-tracking system designed for engineers to manage their projects to an all-purpose issue-tracking solution. As it has matured over time, JIRA has become more than an application—it has transformed into a platform with a suite of other products that are built on it, enabling it to adapt and deliver value to a wide variety of use cases.

Starting with JIRA 7, the term JIRA now refers to a family of products suite, including JIRA Software, JIRA Service Desk, and JIRA Core. With this change, each product is more focused on what they do and the value they bring. It is now easier than ever for customers to choose the product best suited to their needs, whether they are running an Agile software development project, a customer support portal, or simply a generic task management system.

In this book, we will cover all the basics of JIRA and the core capabilities of each product in the family along with the add-ons that add additional features to the JIRA platform.

Packed with real-life examples and step-by-step instructions, this book will help you become a JIRA expert.

What this book covers

This book is organized into eleven chapters. The first chapter starts with setting up your own JIRA, and the subsequent chapters will introduce key features and concepts. With each chapter, you will learn about important concepts such as business processes, workflows, e-mails, and notifications. You will also have the opportunity to put your newly acquired knowledge into practice by following a live JIRA sample implementation.

[Chapter 1, Getting Started with JIRA](#), serves as the starting point of the book and aims to guide you to set up a local copy of a JIRA Software application that will be used throughout the book. For seasoned JIRA experts, this will both refresh your knowledge and also introduce you to the changes in JIRA 7. By the end of this chapter, you should have a running JIRA application.

[Chapter 2, Using JIRA for Business Projects](#), covers using JIRA for projects that are not based on software development, for example, a generic task management solution. This chapter focuses on use the basic features of JIRA, which are offered through the JIRA Core product, which is bundled with JIRA Software.

[Chapter 3, Using JIRA for Agile Projects](#), covers features specific to JIRA Software. This chapter focuses on using JIRA for software development projects, especially using Agile methodologies such as Scrum and Kanban.

[Chapter 4, Issue Management](#), covers everything related to issue creation and the operations that can be performed on an issue (excluding workflow transitions). Furthermore, this chapter touches on the various aspects of issues, as they are the focal point of JIRA. This chapter also serves as an opportunity to show and allow you to set up dummy data that will be used by the sample project.

[Chapter 5, Field Management](#), covers how JIRA collects data through the use of fields and how to expand on this ability through the use of custom fields. This chapter then continues with the various behaviors that can be configured for fields.

[Chapter 6, Screen Management](#), builds on the preceding chapter and explores the concept of screens and how users can create and manage their own screens. This chapter ties in all the previous chapters to show the power behind JIRA's screen design capabilities.

[Chapter 7, Workflow and Business Process](#), explores the most powerful feature offered by JIRA, workflows. The concept of issue life cycles is introduced, and various aspects of workflows explained. This chapter also explores the relationship between workflows and other various JIRA aspects that have been previously covered, such as screens. The concept of JIRA add-ons is also briefly touched upon in the sample project, using some popular add-ons.

[Chapter 8, E-mails and Notifications](#), focuses on how to get automatic e-mail notifications

from JIRA and explores the different settings that can be applied. This is a very important and powerful feature of JIRA and also a critical part of the example project featured in this book. This chapter also ties in the workflow chapter and explains in detail how JIRA manages its notification mechanism.

[Chapter 9, Securing JIRA](#), focuses on the different security control features offered by JIRA. As this topic affects all aspects of JIRA, all previous topics are touched on, explaining how security can be applied to each. It also covers LDAP integration, where you can hook up your JIRA with an existing LDAP system for user management.

[Chapter 10, Searching, Reporting, and Analysis](#), focuses on how data captured in JIRA can be retrieved to provide various types of reporting features. It also covers the changes introduced in JIRA 7.

[Chapter 11, JIRA Service Desk](#), covers the new JIRA Service Desk product from the JIRA 7 product family. It transforms JIRA into a fully fledged service desk solution. This chapter looks at setting up and customizing service desks, integrating with Atlassian Confluence to set up a knowledge base, and defining custom SLA metrics.

What you need for this book

The installation package used in this book will be the Windows Installer standalone distribution, which you can get directly from Atlassian at

<https://www.atlassian.com/software/jira/download> for JIRA Software and

<https://www.atlassian.com/software/jira/service-desk/download> for JIRA Service Desk.

You will also need additional software, including Java SDK, which you can get from <http://www.oracle.com/technetwork/java/javase/downloads/index.html> and MySQL, which you can get from <http://dev.mysql.com/downloads>.

Who this book is for

This book will be especially useful for project managers, but it's also intended for other JIRA users, including developers, and any other industry besides software development who would like to leverage JIRA's powerful task management and workflow features to better manage their business processes.

Conventions

In this book, you will find a number of text styles that distinguish between different kinds of information. Here are some examples of these styles and an explanation of their meaning.

Code words in text, database table names, folder names, filenames, file extensions, pathnames, dummy URLs, user input, and Twitter handles are shown as follows: "Find and open the `web.xml` file in the `JIRA_INSTALL/atlassian-jira/WEB-INF` directory."

A block of code is set as follows:

```
<Connector port="8443" maxHttpHeaderSize="8192" SSLEnabled="true"
maxThreads="150" minSpareThreads="25" maxSpareThreads="75"
enableLookups="false" disableUploadTimeout="true"
acceptCount="100" scheme="https" secure="true"
clientAuth="false" sslProtocol="TLS"      useBodyEncodingForURI="true"/>
```

Any command-line input or output is written as follows:

```
keytool -genkey -alias tomcat -keyalg RSA
```

New terms and **important words** are shown in bold. Words that you see on the screen, for example, in menus or dialog boxes, appear in the text like this: "If you do not have your e-mail server information handy, you can skip this step now by selecting the **Later** option and clicking on **Finish**."

Note

Warnings or important notes appear in a box like this.

Tip

Tips and tricks appear like this.

Reader feedback

Feedback from our readers is always welcome. Let us know what you think about this book—what you liked or disliked. Reader feedback is important for us as it helps us develop titles that you will really get the most out of. To send us general feedback, simply e-mail feedback@packtpub.com, and mention the book's title in the subject of your message. If there is a topic that you have expertise in and you are interested in either writing or contributing to a book, see our author guide at www.packtpub.com/authors.

Customer support

Now that you are the proud owner of a Packt book, we have a number of things to help you to get the most from your purchase.

Errata

Although we have taken every care to ensure the accuracy of our content, mistakes do happen. If you find a mistake in one of our books-maybe a mistake in the text or the code-we would be grateful if you could report this to us. By doing so, you can save other readers from frustration and help us improve subsequent versions of this book. If you find any errata, please report them by visiting <http://www.packtpub.com/submit-errata>, selecting your book, clicking on the **Errata Submission Form** link, and entering the details of your errata. Once your errata are verified, your submission will be accepted and the errata will be uploaded to our website or added to any list of existing errata under the Errata section of that title.

To view the previously submitted errata, go to

<https://www.packtpub.com/books/content/support> and enter the name of the book in the search field. The required information will appear under the **Errata** section.

Piracy

Piracy of copyrighted material on the Internet is an ongoing problem across all media. At Packt, we take the protection of our copyright and licenses very seriously. If you come across any illegal copies of our works in any form on the Internet, please provide us with the location address or website name immediately so that we can pursue a remedy.

Please contact us at copyright@packtpub.com with a link to the suspected pirated material.

We appreciate your help in protecting our authors and our ability to bring you valuable content.

Questions

If you have a problem with any aspect of this book, you can contact us at questions@packtpub.com, and we will do our best to address the problem.

Chapter 1. Getting Started with JIRA

In this chapter, we will start with a high-level view of JIRA, going through each of the components that make up the overall application. We will then examine the various deployment options, system requirements for JIRA 7, and platforms/software that are supported. Finally, we will get our hands dirty by installing our very own JIRA 7 from scratch with the newly improved installation wizard. In the end, we will also cover some post-installation steps, such as setting up SSL to secure our new instance.

By the end of this chapter, you will have learned about the following:

- The different product offerings from the new JIRA 7 family
- The overall architecture of JIRA
- The basic hardware and software requirements to deploy and run JIRA
- Platforms and applications supported by JIRA
- Installing JIRA and all of the required software
- Post-installation configuration options to customize your JIRA

JIRA Core, JIRA Software, and JIRA Service Desk

Starting with JIRA 7, JIRA is split into three different products, and the term JIRA now refers to the common platform that all these products are built on. The three products that make up the new JIRA family are the following:

- **JIRA Core:** This is similar to the classic JIRA, with all the field customizations and workflow capabilities. This is perfect for general-purpose task management.
- **JIRA Software:** This is JIRA Core with agile capabilities (previously known as JIRA Agile). This is well suited for software development teams that want to use agile methodologies, such as Scrum and Kanban.
- **JIRA Service Desk:** This is JIRA Core with service desk capabilities. This is designed for running JIRA as a support ticketing system, with a simplified user interface for the end users, and a focus on customer satisfaction with SLA goals.

As you can see, JIRA Core is at the center, providing all the base functionalities such as user interface customization, workflows, and e-mail notifications, while JIRA Software and JIRA Service Desk add specialized features on top of it.

In this book, we will mostly focus on JIRA Software. However, since JIRA Core provides many of the common features, most of the knowledge is also applicable to JIRA Core, and features that are only available to JIRA Software will be highlighted. For this reason, the term JIRA will be used to cover both JIRA Core and JIRA Software, unless a distinction is required. We will also cover JIRA Service Desk in [Chapter 11, JIRA Service Desk](#).

The JIRA architecture

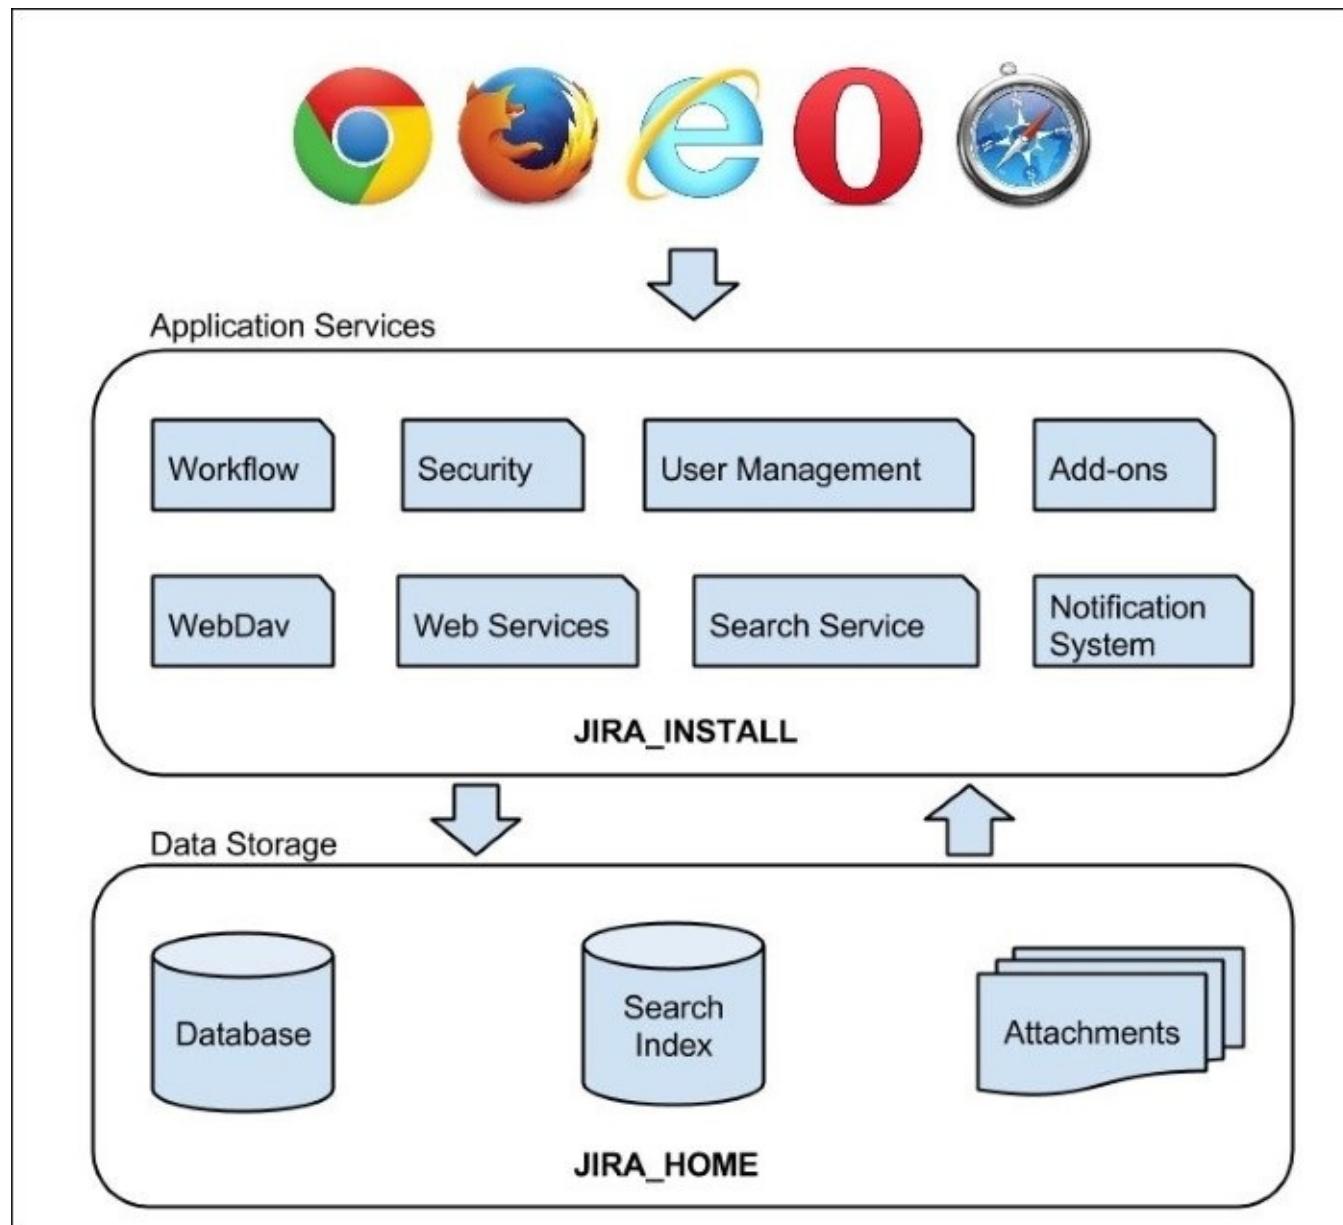

Installing JIRA is simple and straightforward. However, it is important for you to understand the components that make up the overall architecture of JIRA and the installation options available. This will help you make an informed decision and be better prepared for future maintenance and troubleshooting.

High-level architecture

Atlassian provides a comprehensive overview of the JIRA architecture at

<https://developer.atlassian.com/jiradev/jira-platform/jira-architecture/jira-technical-overview>.

However, for the day-to-day administration and usage of JIRA, we do not need to get into details; the information provided can be overwhelming at first glance. For this reason, we have summarized a high-level overview, which highlights the most important components in the architecture, as shown in the following figure:

Web browsers

JIRA is a web application, so there is no need for users to install anything on their machines. All they need is a web browser that is compatible with JIRA. The following table summarizes

the browser requirements for JIRA:

Browsers	Compatibility
Internet Explorer	10.0, 11.0
Mozilla Firefox	Latest stable versions
Safari	Latest stable versions on Mac OSX
Google Chrome	Latest stable versions
Mobile	Mobile Safari Mobile Chrome

Application services

The application services layer contains all the functions and services provided by JIRA. These services include various business functions, such as workflow and notification, which will be discussed in depth in [Chapter 6, Workflows and Business Processes](#) and [Chapter 7, E-mails and Notifications](#), respectively. Other services such as REST/Web Service provide integration points to other applications. The OSGi service provides the base add-on framework to extend JIRA's functionalities.

Data storage

The data storage layer stores persistent data in several places within JIRA. Most business data, such as projects and issues, are stored in a relational database. Content such as uploaded attachments and search indexes are stored in the file system in the `JIRA_HOME` directory, which we will talk about in the next section. The underlying relational database used is transparent to users, and you can migrate from one database to another with ease, as referenced at <https://confluence.atlassian.com/display/JIRA/Switching+Databases>.

The JIRA installation directory

The JIRA installation directory is where you install JIRA. It contains all the executable and configuration files of the application. JIRA neither modifies the contents of the files in this directory during runtime, nor does it store any data files inside the directory. The directory is used primarily for execution. For the remainder of the book, we will refer to this directory as `JIRA_INSTALL`.

The JIRA home directory

The JIRA home directory contains key data and configuration files specific to each JIRA instance, such as JIRA's database connectivity details. As we will see later in this chapter, setting the path to this directory is part of the installation process.

There is a one-to-one relationship between JIRA and this directory. This means each JIRA instance must (and can) have only one home directory, and each directory can serve only one JIRA instance. In the old days, this directory was sometimes called the data directory. It has now been standardized as the JIRA Home. It is for this reason that, for the rest of the book, we will refer to this directory as `JIRA_HOME`.

The `JIRA_HOME` directory can be created anywhere on your system or even on a shared drive. It is recommended to use a fast disk drive with low network latency to get the best performance from JIRA.

This separation of data and application makes tasks such as maintenance and future upgrades an easier process. Within `JIRA_HOME`, there are several subdirectories that contain vital data, as shown in the following table:

Directory	Description
data	This directory contains data that is not stored in the database, for example, uploaded attachment files.
export	This directory contains the automated backup archives created by JIRA. This is different from a manual export executed by a user; manual exports require the user to specify where to store the archive.
import	This directory contains the backups that can be imported. JIRA will only load backup files from this directory.
log	This directory contains JIRA log files, useful to track down errors. Some of the key log files include: <ul style="list-style-type: none">• <code>atlassian-jira.log</code>: Information about JIRA Software and the JIRA Core application.• <code>atlassian-servicedesk.log</code>: Information about the JIRA Service Desk application.• <code>atlassian-jira-security.log</code>: Information about user sessions, logins, and logouts.

plugins	This directory is where installed add-ons are stored. In the previous versions of JIRA, add-ons were installed by copying add-on files to this directory manually; however, in JIRA 7, you will no longer need to do this, unless specifically instructed to do so. Add-ons will be discussed further in later chapters.
caches	This directory contains cache data that JIRA uses to improve its performance at runtime. For example, search indexes are stored in this directory.
tmp	This directory contains temporary files created at runtime, such as file uploads.

When JIRA is running, the `JIRA_HOME` directory is locked. When JIRA shuts down, it is unlocked. This locking mechanism prevents multiple JIRA instances from reading/writing to the same `JIRA_HOME` directory and causing data corruption.

JIRA locks the `JIRA_HOME` directory by writing a temporary file called `jira-home.lock` into the root of the directory. During the shutdown, this file will be removed. However, sometimes JIRA may fail to remove this file, such as during an ungraceful shutdown. In this case, you can manually remove this locked file to unlock the directory so that you can start up JIRA again.

Tip

You can manually remove the locked file to unlock the `JIRA_HOME` directory if JIRA fails to clean it up during the shutdown.

System requirements

Just like any other software application, a set of base requirements needs to be met before you can install and run JIRA. Therefore, it is important for you to be familiar with these requirements so that you can plan out your deployment successfully. Note that these requirements are for a behind-the-firewall deployment, also known as the **JIRA Server**. Atlassian also offers a Cloud-based alternative called **JIRA Cloud**, available at <https://www.atlassian.com/software#cloud-products>.

The cloud version of JIRA is similar to the behind-the-firewall JIRA deployment in most areas, and it is perfect for organizations that do not want to have the overhead of the initial setup and just want to get up-and-running quickly. One major limitation of JIRA Cloud is that you cannot use many of the third-party add-ons available. If you want to have all the power and flexibility of the JIRA Server and worry-free server management, you may consider managed hosting for JIRA offered by third-party vendors.

Hardware requirements

For evaluation purposes, where there will only be a small number of users, JIRA will run happily on any server that has a 1.5 GHz processor and 1 GB to 2 GB of RAM. As your JIRA usage grows, a typical server will have a quad core 2 GHz CPU and 4 GB of RAM dedicated to the JIRA application.

For production deployment, as in most applications, it is recommended that you run JIRA on its own dedicated server. There are many factors that you should consider when deciding the extent of the resources to allocate to JIRA; keep in mind how JIRA will scale and grow. When deciding on your hardware needs, you should consider the following:

- The number of active users in the system
- The number of issues and projects in the system
- The number of configuration items such as custom fields and workflows
- The number of concurrent users, especially during peak hours

It can be difficult at times to estimate these figures. As a reference, a server running with over 2.0 GHz of dual/quad CPU and 2 GB of RAM will be sufficient for most instances with around 200 active users. If you start to get into thousands of active users, you will need to have at least 8 GB of RAM allocated to JIRA (JVM).

Officially, JIRA only supports x86 hardware and 64-bit derivatives of it. When running JIRA on a 64-bit system, you will be able to allocate more than 4 GB of memory to JIRA, the limit if you are using a 32-bit system. If you are planning to deploy a large instance, it is recommended that you use a 64-bit system.

Software requirements

JIRA has four requirements when it comes to software. It needs a supported operating system and a Java environment. It also needs an application server to host and serve its contents and a database to store all of its data. In the following sections, we will discuss each of these requirements and the options that you have to install and run JIRA. You can find the latest information online at <https://confluence.atlassian.com/adminjiraserver071/supported-platforms-802592168.html>.

Operating systems

JIRA supports most of the major operating systems, so the choice of which operating system to run JIRA on becomes a matter of expertise, comfort, and in most cases the existing organization's IT infrastructure and requirements.

The operating systems supported by Atlassian are Windows and Linux. There is a JIRA distribution for Mac OSX, but it is not officially supported. With both Windows and Linux, Atlassian provides an executable installer wizard package, which bundles all the necessary components to simplify the installation process (only available for standalone distribution).

There are minimal differences when it comes to installing, configuring, and maintaining JIRA on different operating systems. If you do not have any preferences and would like to keep the initial cost down, Linux is a good choice.

Java platforms

JIRA is a Java-based web application, so it needs to have a Java environment installed. This can be a **Java Development Kit (JDK)** or a **Java Runtime Environment (JRE)**. The executable installer that comes with Windows or Linux contains the necessary files and will install and configure the JRE for you. However, if you want to use archive distributions, you will need to make sure that you have the required Java environment installed and configured.

JIRA 7 requires Java 8. If you run JIRA on an unsupported Java version, including its patch version, you may run into unexpected errors. The following table shows the supported Java versions for JIRA:

Java platforms	Support status
Oracle JDK/JRE	Java 8 (1.8)

Databases

JIRA stores all its data in a relational database. While you can run JIRA with **HyperSQL Database (HSQLDB)**, the in-memory database that comes bundled with JIRA, it is prone to

data corruption. You should only use this to set up a new instance quickly for evaluation purposes, where no important data will be stored. For this reason, it is important that you use a proper database such as MySQL for production systems.

Most relational databases available on the market today are supported by JIRA, and there are no differences when you install and configure JIRA. Just like operating systems, your choice of database will come down to your IT staff's expertise, experience, and established corporate standards. If you run Windows as your operating system, then you might probably want to go with the Microsoft SQL Server. On the other hand, if you run Linux, then you should consider Oracle (if you already have a license), MySQL, or PostgreSQL.

The following table summarizes the databases that are currently supported by JIRA. It is worth mentioning that both MySQL and PostgreSQL are open source products, so they are excellent options if you are looking to minimize your initial investments.

Database	Support status
MySQL	MySQL 5.1 and newer This requires the latest JDBC driver
PostgreSQL	PostgreSQL 9.0 and newer This requires the latest PostgreSQL driver
Microsoft SQL Server	SQL Server 2008 and newer This requires latest JTDS driver
Oracle	Oracle 12C This requires the latest Oracle driver
HSQLDB	This is bundled with the standalone distribution, for evaluation only

Take a special note of the driver requirement on each database, as some drivers that come bundled with the database vendor (for example, the SQL Server) are not supported.

Application servers

JIRA 7 officially only supports Apache Tomcat as the application server. While it is possible

to deploy JIRA into other application servers, you will be doing this at your own risk, and it is not recommended.

The following table shows the versions of Tomcat supported by JIRA 7:

Application server	Support status
Apache Tomcat	Tomcat 8.0.17 and newer By default, JIRA 7 ships with 8.0.17, so it is recommended that you use that version or newer.

Installation options

JIRA comes in two flavors: an executable installer and a ZIP archive. The executable installer provides a wizard-driven interface that will walk you through the entire installation process. It even comes with a Java installer to save you some time. The ZIP archive flavor contains everything except for a Java installer, which means you will have to install Java yourself. You will also need to perform some post-installation steps manually, such as installing JIRA as a service. However, you do get the advantage of learning what really goes on under the hood.

Installing and configuring JIRA

Now that you have a good understanding of the overall architecture of JIRA, the basic system requirements, and the various installation options, we are ready to deploy our own JIRA instances.

In the following exercise, we will be installing and configuring a fresh JIRA instance for a small production team. We will perform our installation on a Windows platform with a MySQL database server. If you are planning to use a different platform or database, refer to the vendor documentation on installing the required software for your platform.

In this exercise, you will do the following:

- Install a fresh instance of JIRA Software
- Connect JIRA to a MySQL database

We will continue to use this JIRA instance in our subsequent chapters and exercises as we build our help desk implementation.

For our deployment, we will use the following:

- JIRA standalone distribution 7.1.8
- MySQL 5.7.13
- Microsoft Windows 7

Installing Java

Since we will be using the installer package with Java bundled, you can skip this section. However, if you are using the ZIP archive or WAR distribution, you need to make sure that you have Java installed on your system.

JIRA 7 requires JRE version 8 (1.8) or a newer run. You can verify the version of Java you have by running the following command in a Command Prompt:

```
java -version
```

The preceding command tells us which version of Java is running on your system, as shown in the following screenshot:

A screenshot of a Windows Command Prompt window titled 'C:\windows\system32\cmd.exe'. The window contains the following text:
C:\>java -version
java version "1.8.0_11"
Java(TM) SE Runtime Environment (build 1.8.0_11-b12)
Java HotSpot(TM) 64-Bit Server VM (build 25.11-b03, mixed mode)
C:\>

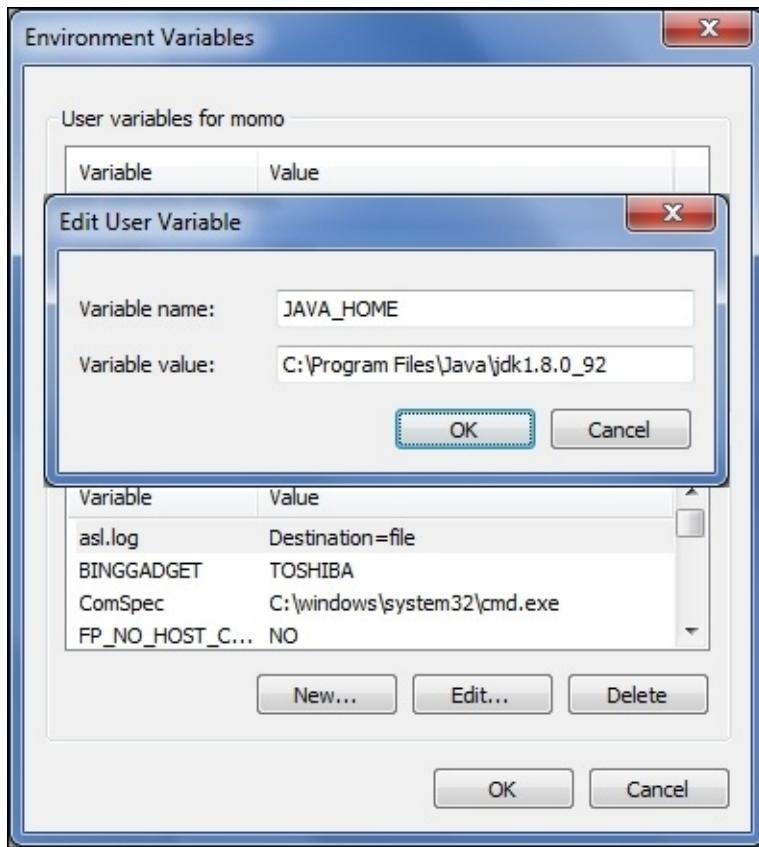

If you do not see a similar output, then chances are you do not have Java installed. You will need to perform the following steps to set up your Java environment. We will start by installing JDK on your system:

1. Download the latest JDK from <http://www.oracle.com/technetwork/java/javase/downloads/index.html>.

Note

At the time of writing this, the latest version of Java 8 is JDK 8 Update 91.

2. Double-click on the downloaded installation file to start the installation wizard.
3. Select where you would like to install Java, or you can simply accept the default values. The location where you install JDK will be referred to as `JAVA_HOME` for the rest of this book.
4. Create a new environment variable named `JAVA_HOME` with the value set to the full path of the location where you installed Java. You can do this as follows:
 1. Open the **System Properties** window by holding down your Windows key and pressing the **Pause** key on your keyboard.
 2. Select the **Advanced system settings** option.
 3. Click on the **Environment Variable** button from the new popup.

5. Edit the PATH environment variable and append the following to the end of its current value:

```
;%JAVA_HOME%\bin
```

6. Test the installation by typing the following command in a new Command Prompt:

```
java -version
```

This will display the version of Java installed, if everything is done correctly. In Windows, you have to start a new Command Prompt after you have added the environment variable to see the change.

Installing MySQL

The next step is to prepare an enterprise database for your JIRA installation. JIRA requires a fresh database. If, during the installation process, JIRA detects that the target database already contains any data, it will not proceed. If you already have a database system installed, then you may skip this section.

To install MySQL, simply perform the following steps:

1. Download MySQL from <http://dev.mysql.com/downloads>, select MySQL Community Server, and then select the MSI installer for Windows.

Note

At the time of writing, the latest version of MySQL is 5.7.13.

2. Double-click on the downloaded installation file to start the installation wizard.
3. Click on **Install MySQL Products** on the welcome screen.
4. Read and accept the license agreement and click on the **Next** button.
5. Select the **Server only** option on the next screen. If you are an experienced database administrator, you can choose to customize your installation. Otherwise, just accept the default values for all subsequent screens.
6. Configure the MySQL root user password. The username will be `root`. Do not lose this password, as we will be using it in the next section.
7. Complete the configuration wizard by accepting the default values.

Preparing MySQL for JIRA

Now that you have MySQL installed, you need to first create a user for JIRA to connect MySQL with, and then create a fresh database for JIRA to store all its data:

1. Start the MySQL Command Line Client by navigating to **Start | All Programs | MySQL | MySQL Server 5.7 | MySQL 5.7 Command Line Client**.

2. Enter the MySQL root user password you set during installation.
3. Use the following command to create a database:

```
create database jiradb character set utf8;
```

4. Here, we are creating a database called `jiradb`. You can name the database anything you like. As you will see later in this chapter, this name will be referenced when you connect JIRA to MySQL. We have also set the database to use UTF-8 character encoding, as this is a requirement for JIRA. Using the following command, you need to ensure that the database uses the InnoDB storage engine to avoid data corruption:

```
grant all on jiradb.* to 'jirauser'@'localhost'  
identified by 'jirauserpassword';
```

We are doing several things here. First, we create a user called `jirauser` and assign the password `jirauserpassword` to him. You should change the username and password to something else.

We have also granted all the privileges to the user for the `jiradb` database that we just created so that the user can perform database operations, such as create/drop tables and insert/delete data. If you have named your database something other than `jiradb`, then make sure that you change the command so that it uses the name of your database.

This allows you to control the fact that only authorized users (specified in the preceding command) are able to access the JIRA database to ensure data security and integrity.

5. To verify your setup, exit the current interactive session by issuing the following command:

```
quit;
```

6. Start a new interactive session with your newly created user:

```
mysql -u jirauser -p
```

7. You will be prompted for a password, which you have set up in the preceding command as `jirauser`.
8. Use the following command:

```
show databases;
```

This will list all the databases that are currently accessible by the logged-in user. You should see `jiradb` among the list of databases.

9. Examine the `jiradb` database by issuing the following commands:

```
use jiradb;  
show tables;
```

The first command connects you to the `jiradb` database, so all of your subsequent commands will be executed against the correct database.

The second command lists all the tables that exist in the `jiradb` database. Right now, the list should be empty, since no tables have been created for JIRA; but don't worry, as soon as we connect to JIRA, all the tables will automatically be created.

Installing JIRA

With the Java environment and database prepared, you can now move on to install JIRA. Normally, there are only two steps:

1. Download and install the JIRA application.
2. Run through the JIRA setup wizard.

Obtaining and installing JIRA

The first step is to download the latest stable release of JIRA. You can download Atlassian JIRA from <http://www.atlassian.com/software/jira/download>.

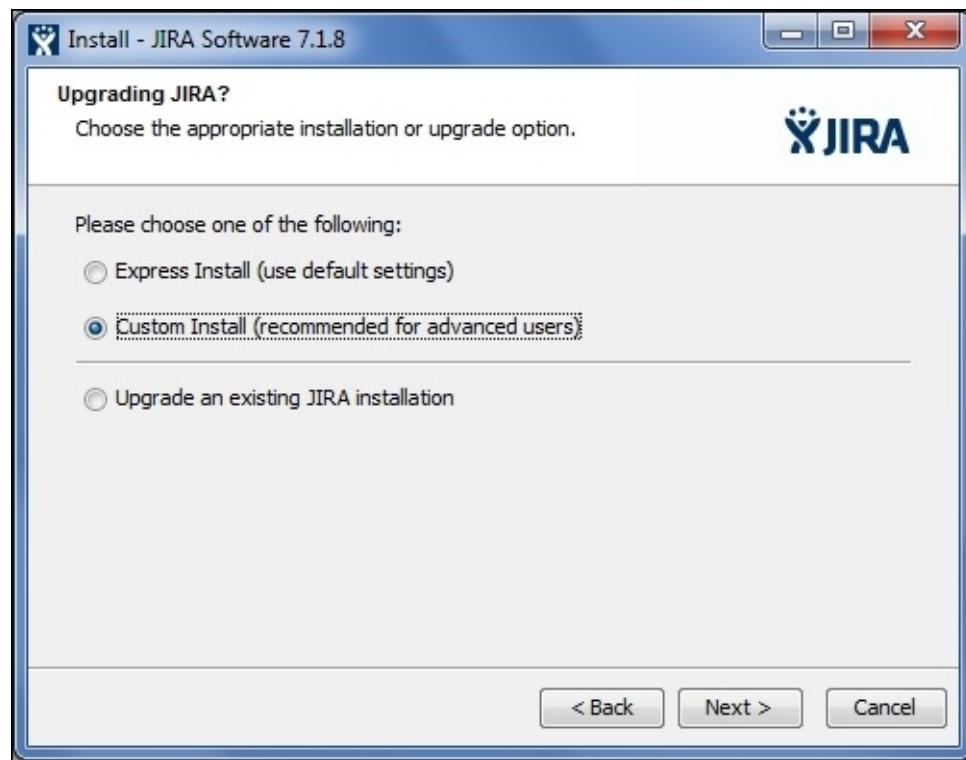

The Atlassian website will detect the operating system you are using and automatically suggest an installation package for you to download. If you intend to install JIRA on a different operating system from the one you are currently on, make sure that you select the correct operating system package.

As mentioned earlier, with Windows there is a Windows installer package and a self-extracting ZIP package. For the purpose of this exercise, we will use the installer package (Windows 64-bit Installer):

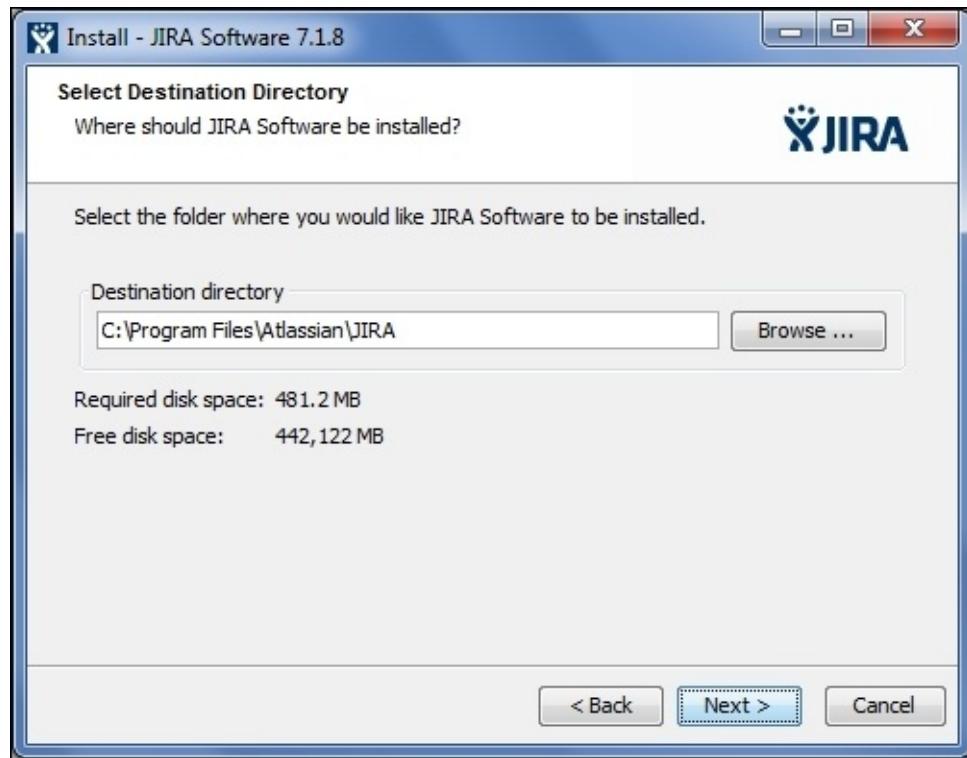

1. Double-click on the downloaded installation file to start the installation wizard and click on the **Next** button to continue.

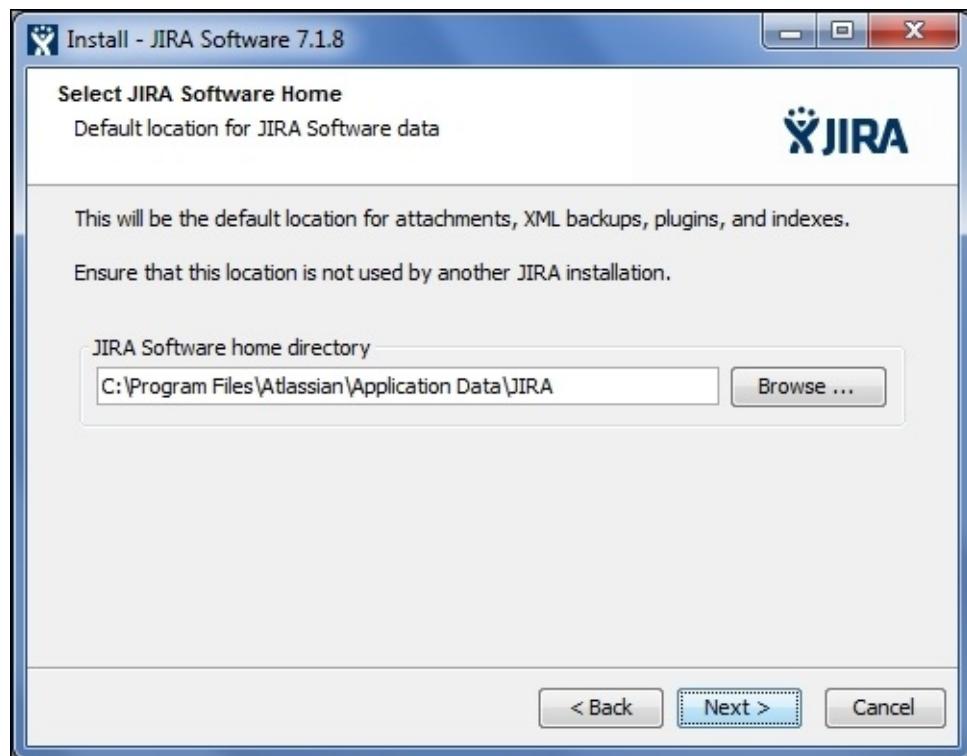

2. Select the **Custom Install** option and click on the **Next** button to continue. Using the custom installation will let us decide where to install JIRA and will also provide many configuration options.

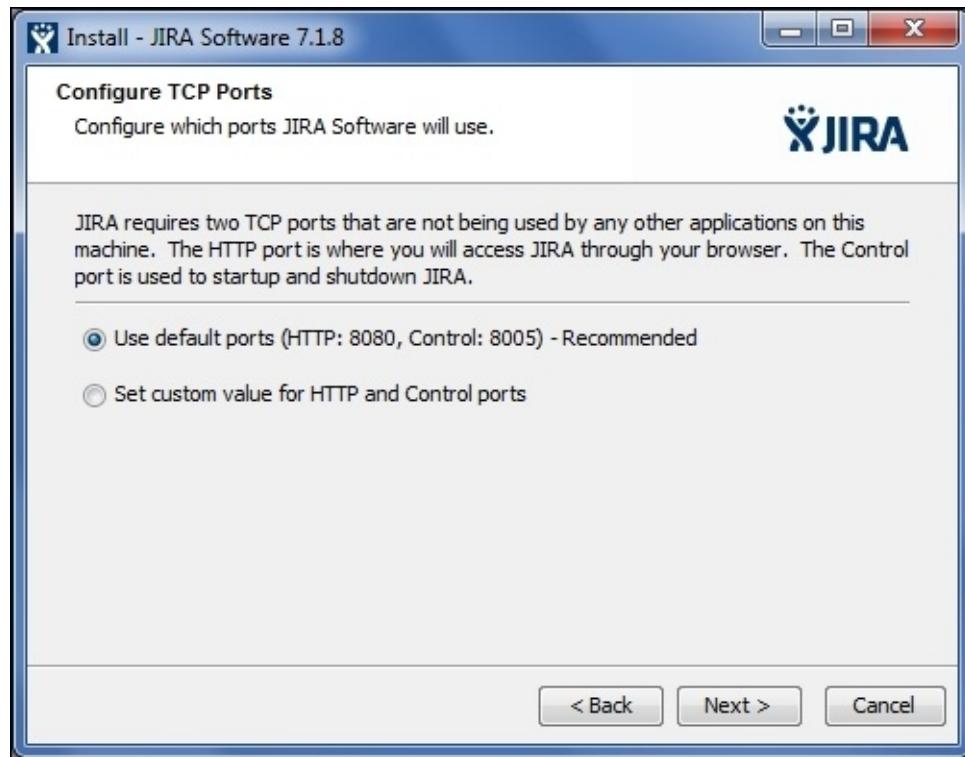

3. Select the directory where JIRA will be installed. This will become the `JIRA_INSTALL` directory. Click on the **Next** button to continue.

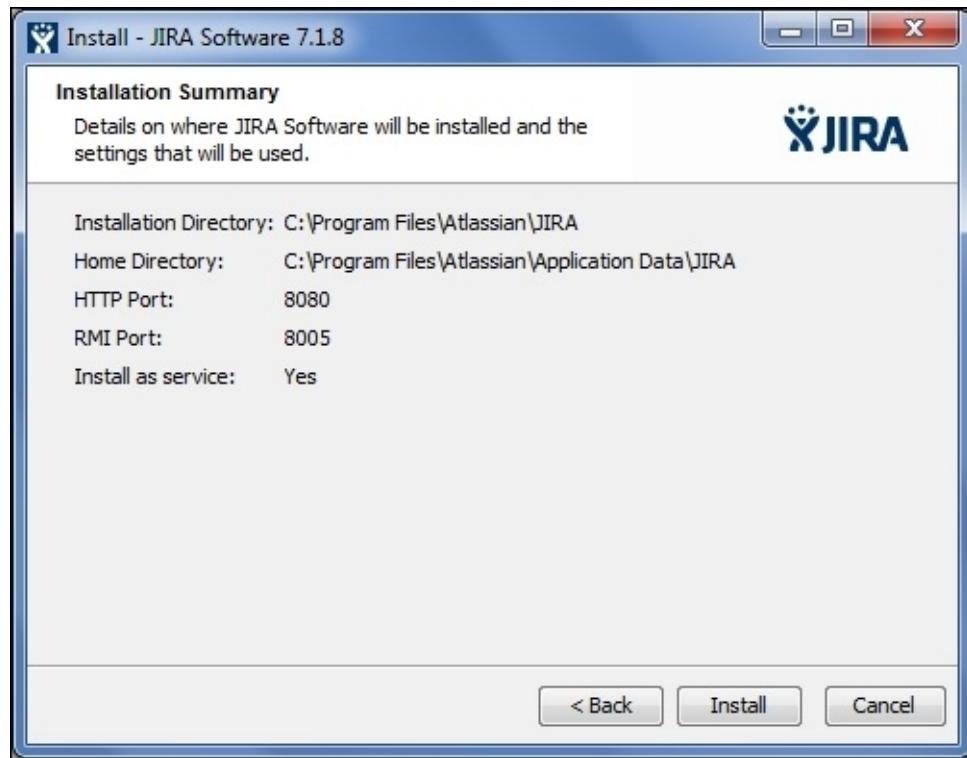

4. Select where JIRA will store its data files, such as attachments and log files. This will become the **JIRA_HOME** directory. Click on the **Next** button to continue.

5. Select where you would like to create shortcuts to the start menu and click on the **Next** button to continue.
6. In the **Configure TCP Ports** step, we need to select the port on which JIRA will be listening for incoming connections. By default, JIRA will run on port 8080. If 8080 is already taken by another application or if you want JIRA to run on a different port such as port 80, select the **Set custom value for HTTP and Control ports** option and specify the port numbers you want to use. Click on the **Next** button to continue.

7. Select whether you would like JIRA to run as a service. If you enable this option, JIRA will be installed as a system service and can be configured to start automatically with the server; see the *Starting and stopping JIRA* section for more details.
8. For the last step, review all the installation options and click on the **Install** button to start the installation.

- Once the installation is complete, check the **Launch JIRA Software in browser** option and click on **Finish**. This will close the installation wizard and open up your web browser to access JIRA. This might take a few minutes to load as JIRA starts up for the first time.

Note

Since we need to install the MySQL database driver for JIRA, we are launching JIRA in the browser now to verify that the installation was successful.

Installing MySQL driver

JIRA does not come bundled with the MySQL database driver, so we have to install it manually. You can download the required driver from <http://dev.mysql.com/downloads/connector/j/>. Once downloaded, you can install the driver by copying the driver JAR file into the `JIRA_INSTALL/lib` directory. After that, you need to restart JIRA. If you have installed JIRA as a Windows service in step 9, refer to the *Starting and stopping JIRA* section.

Note

Make sure that you select the **Platform Independent** option and download the JAR or TAR archive.

The JIRA setup wizard

JIRA comes with an easy-to-use setup wizard that will walk you through the installation and configuration process in six simple steps. You will be able to configure the database connections, default language, and much more. You can access the wizard by opening `http://localhost:<port number>` in your browser, where the `<port number>` is the number you have assigned to JIRA in step 6 of the installation.

In the first step of the wizard, we need to select how we want JIRA to be set up. Since we are installing JIRA for production use, we will select the **I'll set it up myself** option.

Set it up for me

This is the quick setup for **demonstration and evaluation environments**. We'll do most of the JIRA configuration for you, but you **need to be online with a working internet connection** so we can help you generate a JIRA trial license at [MyAtlassian](#). You can change the configuration later if you need to.

I'll set it up myself

Set up and configure your JIRA instance manually. This is recommended for **production environments**, or if you don't have a working internet connection.

Please make sure cookies are enabled before continuing.

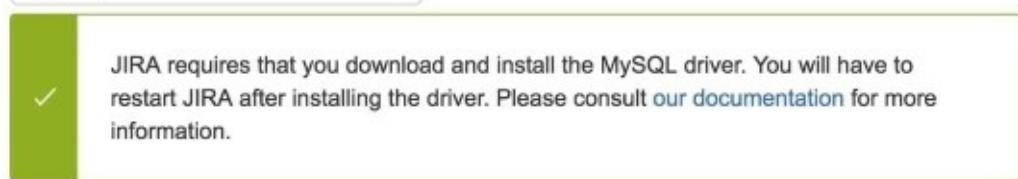

[Next](#)

For the second step, we will need to select the database we want to use. This is where we configure JIRA to use the MySQL database we have created earlier in this chapter. If you select the **Built In** option, JIRA will use its bundled in-memory database, which is good for evaluation purposes. If you want to use a proper database, such as in our case, you should select the **My Own Database** option.

Database setup

Database Connection Built In (for evaluation or demonstration)
 My Own Database (recommended for production environments)
Built in database can be migrated to a database of your own later.
Learn more about connecting JIRA to a database.

Database Type MySQL

Hostname

Hostname or IP address of the database server.

Port

TCP Port Number for the database server.

Database

The name of the database to connect to.

Username

The username used to access the database.

Password

The password used to access the database.

Next

Test Connection

Note

The **Built In** option is great to get JIRA up and running quickly for evaluation purposes.

After you have selected the **My Own Database** option, the wizard will expand for you to provide the database connection details. If you do not have the necessary database driver installed, JIRA will prompt you for it, as shown in the preceding screenshot.

Once you have filled in the details for your database, it is a good idea to first click on the **Test Connection** button to verify that JIRA is able to connect to the database. If everything is set up correctly, JIRA will report a success message. You should be able to move onto the next step by clicking on the **Next** button. This may take a few minutes, as JIRA will now create all the

necessary database objects. Once this is done, you will be taken to step 3 of the wizard.

In the third step, you will need to provide some basic details about this JIRA instance. Once you have filled in the required fields, click on **Next** to move on to step 4 of the wizard.

Set up application properties

Existing data? You can import your data from another installed or hosted JIRA server instead of completing this setup process.

Application Title The name of this installation.

Mode **Private**
Only administrators can create new users.

Public
Anyone can sign up to create issues.

Base URL The base URL for this installation of JIRA.
All links created will be prefixed by this URL.

Next

In the fourth step, we need to provide a license key for JIRA. If you have already obtained a license from Atlassian, you can paste it into the **Your License Key** text box. If you do not have a license, you can generate an evaluation license by clicking on the **generate a JIRA trial license** link. The evaluation license will grant you access to JIRA's full set of features for one month. After the evaluation period ends, you will lose the ability to create new issues, but you can still access your data.

Specify your license key

You need a license key to set up JIRA. Enter your license key or generate a new license key below. You need an account at [MyAtlassian](#) to generate a license key.

Please enter your license key

Server ID **BBQC-3SC2-7QJZ-HXTA**

Your License Key

[or generate a JIRA trial license at MyAtlassian](#)

Next

In the fifth step, you will be setting up the administrator account for JIRA. It is important that you keep the account details somewhere safe and do not lose the password. Since JIRA only stores the hashed value of the password instead of the actual password itself, you will not be able to retrieve it. Fill in the administrator account details and click on **Next** to move on to the sixth step.

Set up administrator account

Enter details for the administrator account. You can add more administrators after setup.

Full name

Email Address

Username

Password

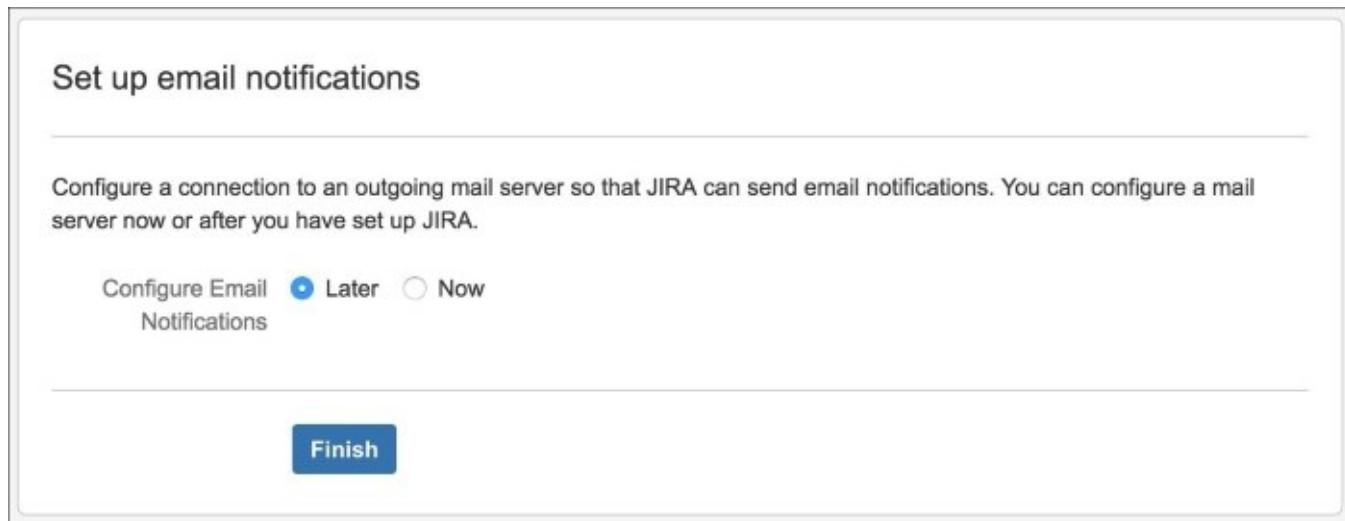

Confirm Password

Next

Tip

This account is important and it can help you troubleshoot and fix problems later on. Do not lose it!

In the sixth step, you can set up your e-mail server details. JIRA will use the information configured here to send out notification e-mails. Notification is a very powerful feature in JIRA and one of the primary methods by which, JIRA communicates with users. If you do not have your e-mail server information handy, you can skip this step now by selecting the **Later** option and clicking on **Finish**. You can configure your e-mail server settings later, as you will see in [Chapter 7, E-mails and Notifications](#).

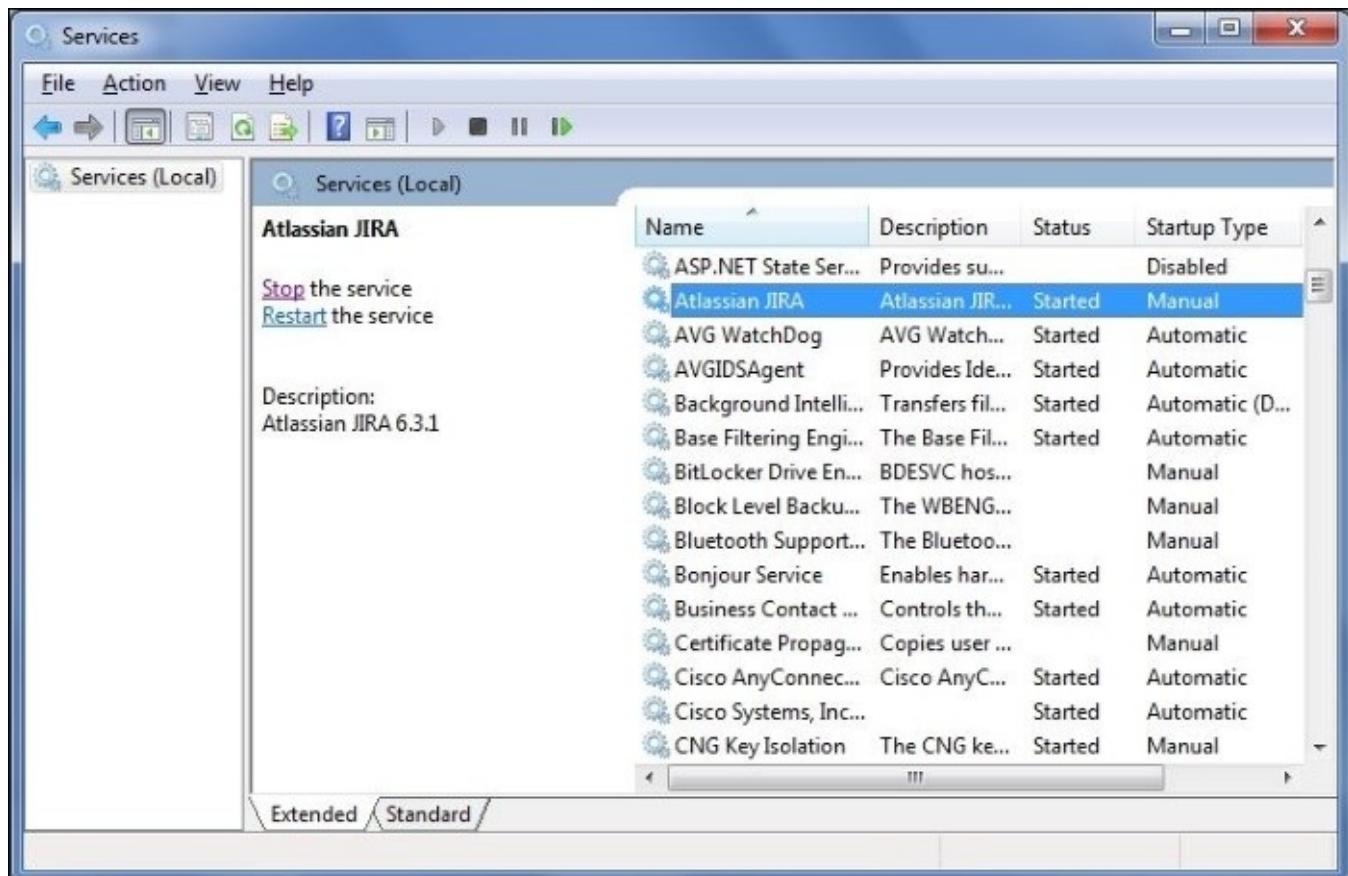

Congratulations! You have successfully completed your JIRA setup. JIRA will then ask you to configure your new account, such as the default language and profile picture. Follow the onscreen prompts to set up your account, and once you are done, you should be presented with the JIRA dashboard, as shown in the following screenshot:

The screenshot shows the JIRA System Dashboard. At the top, there are links for Dashboards, Projects, Boards, Search, Help, Settings, and User Profile. Below the header, the title "System Dashboard" is displayed. The dashboard features three main sections: "Introduction" (with a welcome message, a stylized "X" icon, and customization instructions), "Assigned to Me" (indicating no issues assigned), and "Activity Stream" (showing "Your Company JIRA" and a message "No activity was found").

Starting and stopping JIRA

Since JIRA is installed as a Windows service, you can start, stop, and restart it via the Windows services console by navigating to **Start | Control Panel | Administrative Tools | Services**. In the services console, look for Atlassian JIRA, and you will be able to stop and start the application, as shown in the following screenshot:

Post-installation configurations

The post-installation configuration steps are optional, depending on your needs and environment. If you set up JIRA for evaluation purposes, you probably do not need to perform any of the following steps, but it is always a good practice to be familiar with these as a reference.

Note

You will need to restart JIRA after making the changes discussed in the next section.

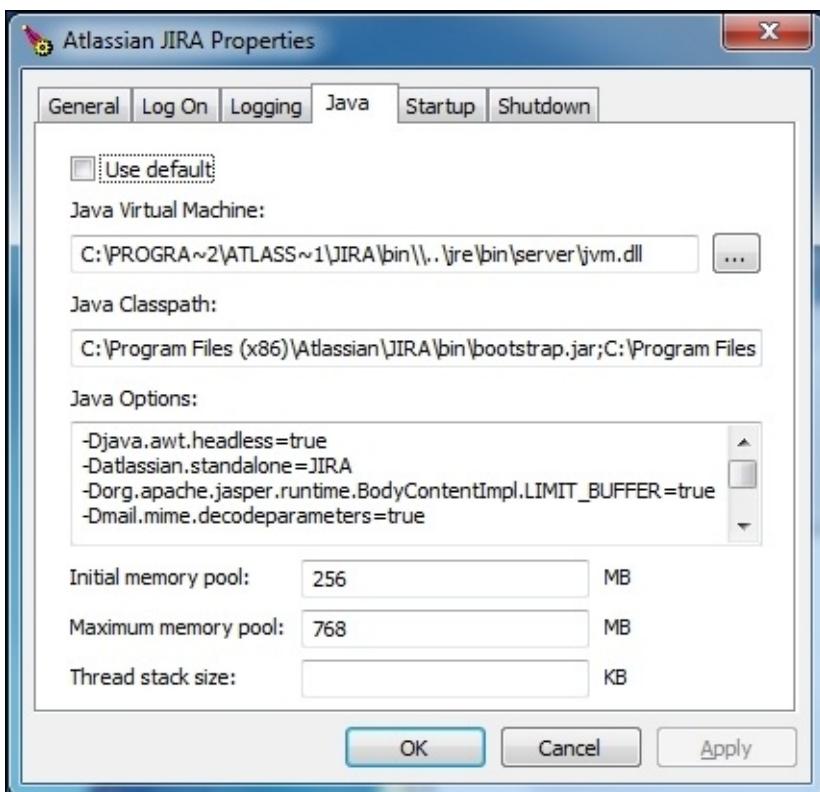

Increasing JIRA's memory

The default memory setting for JIRA is usually sufficient for a small to medium-sized deployment. As JIRA's adoption rate increases, you will find that the amount of memory allocated by default is no longer enough. If JIRA is running as a Windows service, as we described in this chapter, you can increase the memory as follows:

1. Find the JIRA Windows service name. You can do this by going to the Windows services console and double-clicking on the **Atlassian JIRA** service. The service name will be the part after //RS// in the **Path to executable** field, for example, JIRA150215215627.
2. Open a new Command Prompt and change the current working directory to the `JIRA_INSTALL/bin` directory.
3. Run the following command by substituting the actual service name for JIRA:

```
tomcat7w //ES//<JIRA Windows service name>
```

4. Select the **Java** tab, update the **Initial memory pool** and **Maximum memory pool** sizes, and click on **OK**.

5. Restart JIRA to apply the change.

If you are not running JIRA as a Windows service, you need to open the `setenv.bat` file (for Windows) or the `setenv.sh` (for Linux) file in the `JIRA_INSTALL/bin` directory. Then, locate the following lines:

```
set JVM_MINIMUM_MEMORY="384m"  
set JVM_MAXIMUM_MEMORY="768m"
```

Change the value for the two parameters and restart JIRA. Normally, 4 GB (4096m) of memory is enough to support a fairly large instance of JIRA used by hundreds of users.

Tip

Make sure that you have enough physical RAM available before allocating instances to JIRA.

Changing JIRA's port number and context path

As part of the installation process, the installation wizard prompted us to decide which port JIRA should listen to for incoming connections. If you have accepted the default value, it is port 8080. You can change the port setting by locating and opening the `server.xml` file in a text editor in the `JIRA_INSTALL/conf` directory. Let's examine the relevant contents of this file:

```
<Server port="8005" shutdown="SHUTDOWN">
```

This line specifies the port for the command to shutdown JIRA/Tomcat. By default, it is port 8005. If you already have an application that is running on that port (usually another Tomcat instance), you need to change this to a different port:

```
<Connector port="8080" protocol="HTTP/1.1">
```

This line specifies which port JIRA/Tomcat will be running on. By default, it is port 8080. If you already have an application that is running on that port, or if the port is unavailable for some reason, you need to change it to another available port:

```
<Context path="/jira" docBase="${catalina.home}/atlassian-jira"  
reloadable="false" useHttpOnly="true">
```

This line allows you to specify the context that JIRA will be running under. By default, the value is empty, which means JIRA will be accessible from `http://hostname:portnumber`. If you decide to specify a context, the URL will be `http://hostname:portnumber/context`. In our example here, JIRA will be accessible from `http://localhost:8080/jira`.

Configuring HTTPS

By default, JIRA runs with a standard, non-encrypted HTTP protocol. This is acceptable if you are running JIRA in a secured environment, such as an internal network. However, if you plan to open up access to JIRA over the Internet, you will need to tighten up the security by encrypting sensitive data, such as usernames and passwords that are being sent, by enabling HTTPS (HTTP over SSL).

For a standalone installation, you will need to perform the following tasks:

1. Obtain and install a certificate.
2. Enable HTTPS on your application server (Tomcat).
3. Redirect traffic to HTTPS.

First, you need to get a digital certificate. This can be obtained from a certification authority, such as VeriSign (CA certificate), or a self-signed certificate generated by you. A CA certificate will not only encrypt data for you, but also identify your copy of JIRA to the users. A self-signed certificate is useful when you do not have a valid CA certificate and you are only interested in setting up HTTPS for encryption. Since a self-signed certificate is not signed by a certification authority, it is unable to identify your site to the public and users will be prompted with a warning that the site is untrusted when they first visit it. However, for evaluation purposes, a self-signed certificate will suffice until you can get a proper CA certificate.

For the purpose of this exercise, we will create a self-signed certificate to illustrate the complete process. If you have a CA certificate, you can skip the following steps.

Java comes with a handy tool for certificate management, called **keytool**, which can be found in the `JIRA_HOME\jre\bin` directory if you are using the installer package. If you are using your own Java installation, then you can find it in `JAVA_HOME\bin`.

To generate a self-signed certificate, run the following commands from a Command Prompt:

```
keytool -genkey -alias tomcat -keyalg RSA  
keytool -export -alias tomcat -file file.cer
```

This will create a keystore (if one does not already exist) and export the self-signed certificate (`file.cer`). When you run the first command, you will be asked to set the password for the keystore and Tomcat. You need to use the same password for both. The default password is `changeit`. You can specify a different password of your choice, but you then have to let JIRA/Tomcat know, as we will see later.

Now that you have your certificate ready, you need to import it into your trust store for Tomcat to use. Again, you will use the keytool application in Java:

```
keytool -import -alias tomcat -file file.cer
```

JIRA_HOME\jre\lib\security\cacerts

This will import the certificate into your trust store, which can be used by JIRA/Tomcat to set up HTTPS.

To enable HTTPS on Tomcat, open the `server.xml` file in a text editor from the `JIRA_INSTALL/conf` directory. Locate the following configuration snippet:

```
<Connector port="8443" maxHttpHeaderSize="8192" SSLEnabled="true"
maxThreads="150" minSpareThreads="25" maxSpareThreads="75"
enableLookups="false" disableUploadTimeout="true"
acceptCount="100" scheme="https" secure="true"
clientAuth="false" sslProtocol="TLS"      useBodyEncodingForURI="true"/>
```

This enables HTTPS for JIRA/Tomcat on port 8443. If you have selected a different password for your keystore, you will have to add the following line to the end of the preceding snippet before the closing tag:

```
keystorePass=""
```

The last step is to set up JIRA so that it automatically redirects from a non-HTTP request to an HTTPS request. Find and open the `web.xml` file in the `JIRA_INSTALL/atlassian-jira/WEB-INF` directory. Then, add the following snippet to the end of the file before the closing `</web-app>` tag:

```
<security-constraint>
  <web-resource-collection>
    <web-resource-name>all-except-attachments</web-resource-name>
    <url-pattern>*.js</url-pattern>
    <url-pattern>*.jsp</url-pattern>
    <url-pattern>*.jspx</url-pattern>
    <url-pattern>*.css</url-pattern>
    <url-pattern>/browse/*</url-pattern>
  </web-resource-collection>
  <user-data-constraint>
    <transport-guarantee>CONFIDENTIAL</transport-guarantee>
  </user-data-constraint>
</security-constraint>
```

Now, when you access JIRA with a normal HTTP URL, such as `http://localhost:8080/jira`, you will be automatically redirected to its HTTPS equivalent, `https://localhost:8443/jira`.

Summary

JIRA is a powerful yet simple application as reflected in its straightforward installation procedures. You have a wide variety of options to choose how you would like to install and configure your copy. You can mix-and-match different aspects, such as operating systems and databases, to best suit your requirements. The best part is that you can have a setup that consists entirely of open source software, which will bring down the cost and provide you with a reliable infrastructure at the same time.

In the next chapter, we will start to explore various aspects of JIRA. The following chapters, starting with projects, will talk about key concepts in any JIRA installation.

Chapter 2. Using JIRA for Business Projects

JIRA initially started off as a bug-tracking system, helping software development teams to better track and manage the problems/issues in their projects. Over the years, JIRA has expanded on the concept and capabilities of projects by adding support for agile and later letting you run projects as a public facing service desk, each with its own features and user interface. With all these new additions, it became a bit confusing, especially to newcomers. So starting with JIRA 7, Atlassian has made improvements to help streamline how a project is used and help users to get started quickly.

In this chapter, we will focus on the most basic project type, the business project, which is available to all three JIRA applications, Core, Software, and Service Desk. We will then take a look at the various user interfaces that JIRA has for working with projects, both as an administrator and an everyday user. We will also introduce permissions for the first time in the context of projects and will expand on this in later chapters. Business project being the basic project type, most concepts covered in this chapter will be applicable to the more specialized types.

By the end of this chapter, you will learn the following:

- JIRA project types and templates
- Different user interfaces for project management in JIRA
- How to create new projects in JIRA
- How to import data from other systems into JIRA
- How to manage and configure a project
- How to manage components and versions

Understanding project types

Starting with JIRA 7, a new concept called **project type** is introduced. Project types define the features available for your projects as well as the user interface that will be used to present information within the projects. Each project type also comes with one or more **templates**, with a set of predefined configurations to help you get started quickly. The following screenshot shows you the project types and their templates from an out-of-the-box JIRA Software installation.

The screenshot shows the 'Create project' screen in JIRA Software. At the top, there's a header with 'Create project' on the left and 'View Marketplace Workflows' on the right. Below the header, there are two main sections: 'SOFTWARE' and 'BUSINESS'. Under 'SOFTWARE', there are three templates: 'Scrum software development' (selected), 'Basic software development', and 'Kanban software development'. Each template has a brief description and an icon. Under 'BUSINESS', there are two templates: 'Project management' and 'Process management'. Each template has a brief description and an icon. At the bottom of the screen, there are buttons for 'Import a project' and 'Create with shared configuration', and a 'Next' button followed by a 'Cancel' button.

Project Type	Template	Description	Icon
SOFTWARE	Scrum software development	Agile development with a board, sprints and stories. Connects with source and build tools.	
	Basic software development	Track development tasks and bugs. Connects with source and build tools.	
	Kanban software development	Optimise development flow with a board. Connects with source and build tools.	
BUSINESS	Project management	Plan, track and report on all of your work within a project.	
	Process management	Track all the work activity as it transitions through a streamlined process.	

Note

Templates under **Software** are included in JIRA Software. If you are running JIRA Core instead, you will only have templates under **Business**.

If you create a project using the **Scrum software development** template under the **Software** project type, your project will come with a scrum board and a set of configurations designed to work with the scrum methodology. On the other hand, if you choose the **Task management** template under the **Business** project type, your project will have a different user interface designed for task management.

Business projects

As we have already seen, JIRA comes with a number of project types, depending on what applications you have installed. The business project type, being part of JIRA Core, is available to all installations.

Business projects are very similar to how JIRA worked before JIRA 7, where it worked as a highly customizable, generic task-tracking system. The focus of the business project type and its templates is on enabling users to easily create tasks and track and report their progress.

Out-of-the-box, you have three built-in templates, each with a set of predefined configurations such as workflows and fields, to give you some idea of how to set up your projects. You can use them as-is or customize them further, based on your needs.

JIRA permissions

Before we start working with projects in JIRA, we need to first understand a little bit about permissions. Permissions are a big topic, and we will cover it in detail in [Chapter 9, Securing JIRA](#). For now, we will briefly talk about permissions related to creating and deleting, administering, and browsing projects.

In JIRA, users with the JIRA administrator permission will be able to create and delete projects. By default, users in the jira-administrators group have this permission, so the administrator user we created during the installation process in [Chapter 1, Getting Started with JIRA](#), will be able to create new projects. We will refer to this user and any other users with this permission as a JIRA Administrator.

For any given project, users with the **Administer Project** permission for that project will be able to administer the project's configuration settings. As we will see in the later sections of this chapter, this means that users with this permission will have access to the **Project Administration** interface for a given project. This allows them to update the project's details, manage versions, and components, view configurations such as the workflow used by the project, and decide who will be able to access this project. By default, the JIRA Administrator will have this permission.

If a user needs to browse the contents of a given project, then they must have the **Browse Project** permission for that project. This means that the user will have access to the project browser interface for the project. By default, the JIRA Administrator will have this permission.

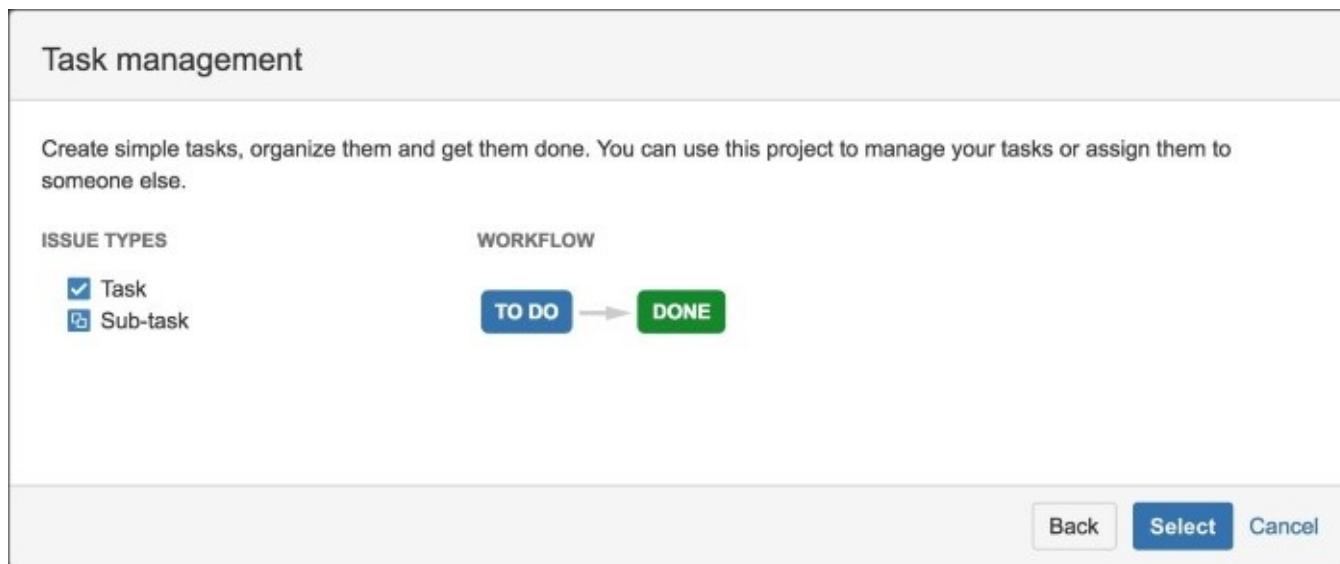

Creating projects

To create a new project, the easiest way is to select the **Create Project** menu option from the **Projects** drop-down menu from the top navigation bar. This will bring up the **Create project** dialog. Note that, as we explained, you need to be a JIRA Administrator (such as the user we created during installation) to create projects. This option is only available if you have the permission.

From the **Create project** dialog, select the template you want to use under the **Business** heading and click on **Next**. On the next page, JIRA will display pre-defined configurations for the template you have selected. In our example, we have selected the Task management template, so JIRA provides us with two issue types, and a very simple workflow with two steps. Click on the **Select** button to continue.

Note

JIRA will create new configuration schemes based on the selected template once the new project is created.

Note

You can change these configurations once the project is created.

For the third and last step, we need to provide the new project's details. JIRA will help you validate the details, for example, by making sure that the project key conforms to the configured format. After filling in the project details, click on the **Submit** button to create the new project.

Task management

Name

Max. 80 characters.

Key 

Max. 10 characters.

Project Lead 

Enter the username of the Project Lead.

[Back](#)

[Submit](#)

[Cancel](#)

The following table lists the information you need to provide when creating a new project:

Field	Description
Name	This is a unique name for the project.
Key	<p>This is a unique identity key for the project. As you type the name of your project, JIRA will auto-fill the key based on the name, but you can replace the auto-generated key with one of your own. You will be able to change the key later.</p> <p>The project key will also become the first part of the issue key for issues created in the project.</p>
Project Lead	The lead of the project can be used to auto-assign issues. Each project can have only one lead. This option is available only if you have more than one user in JIRA.

Once you have created the new project, you will be taken to the **Project Browser** interface, which we will discuss in the forthcoming sections.

Changing the project key format

When creating new projects, you may find that the project key needs to be in a specific format and length. By default, the project key needs to adhere to the following criteria:

- It should contain at least two characters
- It cannot be more than 10 characters in length
- It should contain only characters, that is, no numbers

You can change the default format to have less restrictive rules.

Note

These changes are for advanced users only.

First, to change the project key length, perform the following steps:

1. Browse to the JIRA Administration console.
2. Select the **System** tab and then the **General configuration** option.
3. Click on the **Edit Settings** button.
4. Change the value for the **Maximum project key size** option to a value between 2 and 255 (inclusive) and click on the **Update** button to apply the change.

Changing the project key format is a bit more complicated. JIRA uses a regular expression to define what the format should be. To change the project key format, use the following steps:

1. Browse to the JIRA Administration console.
2. Select the **System** tab and then the **General configuration** option.
3. Click on the **Advanced Settings** button.
4. Hover over and click on the `([A-Z][A-Z]+)` value for the **jira.projectkey.pattern** option. For example, if you want to use numbers in your project key, you can use `([A-Z][A-Z0-9]+)`.
5. Enter the new regular expression for the project key format and click on **Update**.

There are a few rules when it comes to setting the project key format:

- The key must start with a letter
- All letters must be uppercase, that is, `(A-Z)`
- Only letters, numbers, and the underscore character can be used
- The new pattern must be compatible with all existing projects

Project user interfaces

There are two distinctive interfaces for projects in JIRA. The first interface is designed for everyday users, providing useful information on how the project is going with reports and statistics, called **project browser**.

The second interface is designed for project administrators to control project configuration settings, such as permissions and workflows, and called **Project Administration**.

After creating a project, the first interface you see will be project browser. We will start our discussion around this interface and then move on to the **Project Administration** interface.

Project browser

Project browser is the interface that most users will use with JIRA. It acts as the home page of the project, providing useful information, such as recent activities in the project, reports, and information from other connected systems, such as source control and continuous integration. The actual project browser interface depends on the project type, so it will vary from project to project. For example, the scrum software development project will display an agile board as its default view, as shown in the following screenshot:

The screenshot shows the JIRA interface for a Scrum project. The left sidebar has a 'Scrum board' icon and a 'Backlog' link. The main area is titled 'Backlog' with '11 issues'. Each issue is listed with a green checkmark icon, a title like 'SCRUM-1 As a scrum master, I can see the progress of a sprint via the Burndown Chart >> Click "Reports" to view the Burndown Chart', and a 'Create Sprint' button. The interface includes filters for 'QUICK FILTERS: Only My Issues' and 'Recently Updated'.

For business projects such as general task management, project browser will display an activity stream showing the latest updates in the project, as shown in the following screenshot:

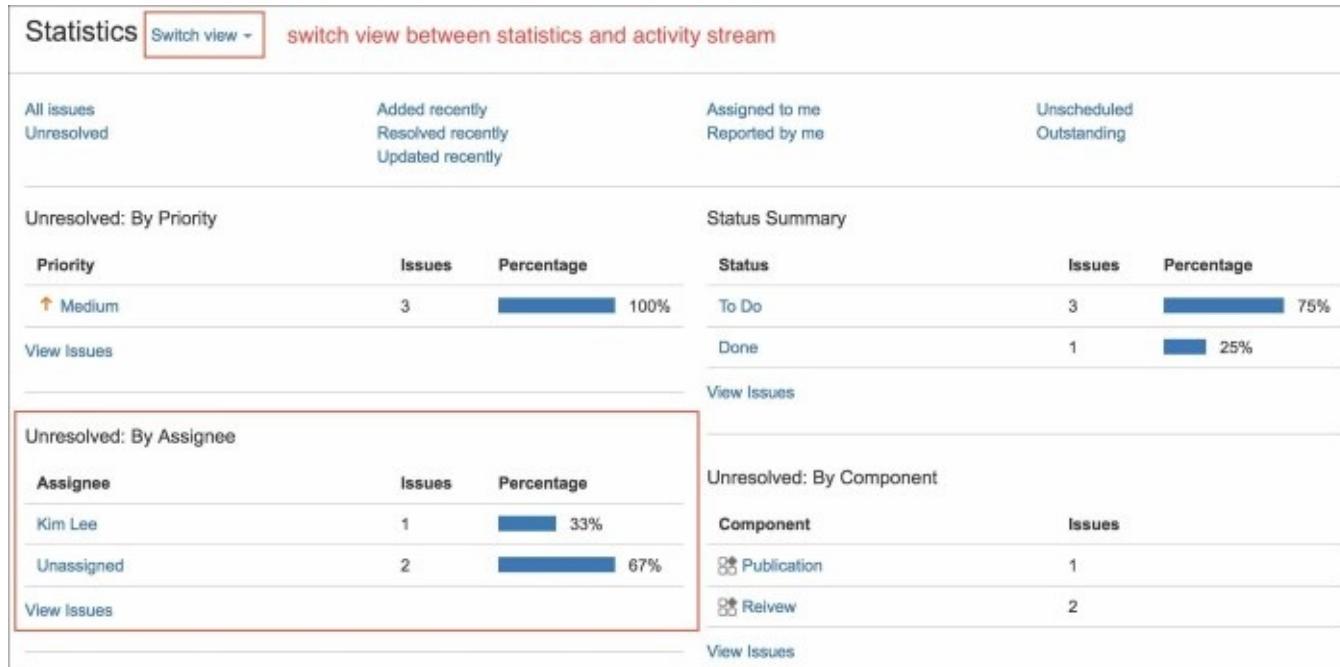

The screenshot shows the JIRA interface for a general task management project. The left sidebar has a 'Publication Tasks' icon and an 'Issues' link. The main area is titled 'Activity' with a 'Switch view +' button. It shows a timeline of updates: 'Tom Johnson changed the Due Date to '16/Jul/16' on PUB-1 - Review author TOC for #HK_3000', 'Patrick Li changed the status to Done on PUB-4 - Update review guideline to include latest updates with a resolution of 'Done'', 'Kim Lee changed the Assignee to 'Kim Lee' on PUB-3 - Contact author for second review', 'Kim Lee created PUB-4 - Update review guideline to include latest updates', 'Tom Johnson created PUB-3 - Contact author for second review', 'Patrick Li created PUB-2 - Send contract document for #CON_7829', 'Patrick Li created PUB-1 - Review author TOC for #HK_3000', and 'Patrick Li created PUB-1 - Review author TOC for #HK_3000'. Each update includes a timestamp, a user icon, and options to 'Comment', 'Vote', and 'Watch'.

To access the **Project Browser** interface, simply select the project from the **Projects** drop-down or the project list via the **View All Projects** option. Note that you will also need to have the **Browse Project** permission. The project browser is made up of several tabs, which are listed here along with their descriptions:

Project Browser tab	Description
Summary	This displays a quick overview of the project. It comes in two views: an activity view and a statistics view.
Issues	This displays a breakdown of issues in the project grouped by attributes, such as priority and status.
Reports	This contains a number of built-in and custom reports that you can generate based on the issues in the project. The types of report available will vary depending on the project type.
Versions	This displays the summary of versions of the project. This tab is only available when versions are configured.
Components	This displays a summary of components and their related issues. This tab is only available when components are configured for the project.
Project Shortcuts	This lets you add custom links that will act as bookmarks to provide more information on the project.

The Summary tab

The **Summary** tab provides you with a single-page view into the project you are working on. It provides an activity view, which will display the latest activities that are happening in the project, and a statistics view, which provides you with a number of useful breakdowns of issues within the project. For example, **Unresolved: By Assignee** lets you know how many open issues are assigned to each user, allowing the project team to better plan their resource allocation, as shown in the following screenshot:

The Issues tab

The **Issues** tab, by default, lists all open issues in the project. It also contains a number of other predefined filters you can use to look for issues. From the list, you can select an individual issue and get more information, as shown in the following screenshot:

The screenshot shows the JIRA interface. On the left, there's a sidebar with various project-related links like 'Publication Tasks', 'Summary', 'Issues', 'Reports', 'Versions', 'Components', 'PROJECT SHORTCUTS', 'TOC Documents', 'Review Guideline', 'Contract Documents', and 'Add link'. Below these is a 'Give feedback' section.

The main area is titled 'Open Issues' with a dropdown menu showing 'My Open Issues' (selected), 'Order by Priority', 'Reported by Me', 'Recently Viewed', 'All Issues', 'Open Issues' (selected), 'Added recently', 'Resolved recently', 'Updated recently', 'Highest priority and open', 'Due this week', and 'Manage Filters'.

A specific issue, 'Review author TOC for #HK_3000', is selected. The right side shows its details: Type: Task, Status: TO DO (View Workflow), Priority: Medium, Resolution: Unresolved, Affects Version/s: None, Fix Version/s: None, Component/s: None, Labels: None. It has a description placeholder 'Click to add description'.

On the right, there are sections for 'People' (Assignee: Unassigned, Reporter: Patrick Li, Votes: 0, Watchers: Stop watching this issue), and 'Dates' (Due: 18Jul'16, Created:).

The Versions and Components tabs

The **Versions** and **Components** tabs list all the available versions and components that have been configured for this project, respectively. They are only visible if the project contains versions and/or components.

The Project Administration interface

The **Project Administration** interface is where project administrators can manage the settings and configurations of their projects. For example, you can change the project's name, select what issue types will be available for the project, and manage a list of components within the project. Only users with the **Administer Projects** permission for a given project will be able to access this interface.

To access the **Project Administration** interface, use the following steps:

1. Go to the project browser for the project you want to administer.
2. Select the **Project Administration** option in the bottom-left corner. If you do not see the option, then you do not have the necessary permission.

From the **Project Administration** interface, if you are a JIRA Administrator (such as the user created during installation), you will be able to perform the following key operations:

- Update project details, such as project name, description, avatar, and type
- Manage what users see when working on the project, such as issue types, fields, and screens
- Control permission settings and notifications
- Manage the list of available components and versions

Note

If you are not a JIRA Administrator (that is, if you do not have the JIRA Administrator global permission), you can only view the current project's configuration. We will cover permissions in [Chapter 9, Securing JIRA](#).

The preceding key operations are shown in the following screenshot:

The screenshot shows the JIRA Project Administration interface for the 'Publication Tasks' project. The top navigation bar includes links for Dashboards, Projects, Issues, Boards, Create, and a user profile. The main header displays the project key (PUB), lead (Patrick Li), project type (Business), category (None), and URL (No URL). A red box highlights the 'Administration' link in the top right corner. The left sidebar lists project configuration options: Issue types, Workflows, Screens, Fields, Versions, Components, Users and roles, Permissions, Issue Security, and Notifications. The 'Issue types' section is expanded, showing a summary table with rows for Sub-task and Task. The 'Versions' section shows three versions: 2.0, 1.1, and 1.0 (Release 09Jul/16). The 'Components' section lists Print, Publication, and Review. A red box highlights the 'Edit Project' button in the top right of the main content area. The overall interface is light blue and white, with red highlights for specific sections.

As an administrator, this is where you will be applying customizations to your project. We will look at these customizations in later chapters.

The Summary tab

The first group consists of a single tab, the **Summary** tab. On this tab, JIRA displays a single-page view of all the current configuration settings for the project. Not all the settings will have their own tabs.

On this tab, you can do the following:

- Update the project's general information, including the project key and type
- Set the category for this project, so it can be grouped together with other similar projects.
- Re-index the project when the search index is out of sync
- Delete the project

The Components tab

The **Components** tab is where project administrators can manage the components for their projects. Components can be thought of as subsections that make up the full project. In a business project, components can be various business functions or operations that need to be completed. As shown in the following screenshot, there are three components configured in the current project:

The screenshot shows the 'Components' tab in JIRA. At the top, there's a header with icons for creating components and a title 'Components'. Below the header, a sub-header says 'Projects can be broken down into components, e.g. "Database", "User Interface". Issues can then be categorised against different components.' A table follows, with columns: Name, Description, Component Lead, and Default Assignee. There are three rows of data:

Name	Description	Component Lead	Default Assignee
Print		Patrick Li	Project Default (Unassigned) <button>Add</button>
Publication	click to edit	Tom Johnson	Project Default <button>Delete</button>
Review		Kim Lee	Project Default <button>Delete</button>

In JIRA, components are project-specific. This means that components from one project cannot be used in a different project. This also allows each project to maintain its own sets of components. A component has four pieces of information, as shown in the following table:

Field	Description
Name	This is a unique name for the component.
Description	This is an optional description to offer more explanation on what the component is for.
Component Lead	This is an optional field where you can select a single user as the lead for the component. For example, in a software project, this can be the main developer for the component.
Default Assignee	This tells JIRA when an issue is created without the assignee being selected. If the issue has a component, then JIRA will auto-assign the issue to the selected default assignee.

Creating components

Unlike some older versions of JIRA, you can create new components directly on the page:

1. Browse to the **Components** tab for the project.
2. Provide a unique name for the component. JIRA will let you know whether the name is already taken.
3. Provide a short description for the new component.
4. Select a user to be the lead of the component. Just start typing and JIRA will prompt you with options that meet the criteria.
5. Select the default assignee option for the component.
6. Click on **Add** to create the new component.

Once you have created the new component, it will be added to the list of existing components. When a component is first created, it will be placed at the top of the list. If you refresh the page, the list will then be ordered alphabetically.

The component lead and a default assignee

One of the useful features of components is the ability to assign a default assignee to each component. This means that when a user creates an issue with a component and sets the assignee as Automatic, JIRA will be able to automatically assign the issue based on the component selected. This is a very powerful feature for organizations where members of various teams often do not know each other. Therefore, when it comes to assigning issues at creation time, it is difficult to decide who to assign them to. With this feature, it can be set up so that the lead of the component becomes the default assignee and the issues raised can then be delegated to other members of the team.

Note

If the issue has more than one component with a default assignee, the assignee for the first component in alphabetical order will be used.

The Versions tab

Like the **Components** tab, the **Versions** tab allows project administrators to manage versions for their projects. Versions serve as milestones for a project. In project management, versions represent points in time. While, for projects that are not product-oriented, versions may seem less relevant, versions can still be valuable when it comes to managing and tracking the progress of issues and work.

As with components, versions also have a number of attributes, as shown in the following table:

Field	Description
Name	This is a unique name for the version.
Description	This is an optional description to offer more explanation on what the version is for.
Start Date	This is a date indication that states when work on this version is expected to start.
Release Date	This is an optional date that will be marked as the scheduled date to release the version. Versions that are not released according to the release date will have the date highlighted in red.

Creating versions

Creating new versions is as simple as providing the necessary details for the new version and clicking on the **Add** button:

1. Browse to the **Versions** tab for the target project.
2. Provide a unique name for the version (for example, `1.1.0`, `v2.3`). JIRA will let you know whether the name is already taken.
3. Provide a short description for the new version.
4. Select the date on which the version starts and will be released using the date picker.
5. Click on **Add** to create the new version.

Unlike components, versions will not be ordered automatically by JIRA, so you will have to manually maintain the order. To change the order of versions, all you have to do is hover your mouse pointer to the left of the version, and you will be able to drag the version up and down the list.

Managing versions

When you hover over a version, you will notice that there is a little cog icon to the right. If you click on that, you will have the options to do the following:

Option	Description
Release	<p>This will mark the version as released, meaning that it is completed or shipped. When you release a version, JIRA will automatically check to make sure that all the issues are completed for the selected version. If these are incomplete, you will be prompted to either ignore those issues or push them to a different version.</p> <p>If the version has already been released, it will change to Unrelease.</p>
Build and Release	<p>This is similar to the Release option, but it also performs a build through Atlassian Bamboo if there are any software codes. The version will only be released if the build is successful.</p> <p>This option is not available if the version is already released.</p>
Archive	<p>This will mark the version as archived, meaning that the version is stored away until further notice. When a version is archived, you cannot release or delete it until it is unarchived.</p>
Delete	<p>This will delete the version from JIRA. Again, JIRA will search for issues that are related to this version and ask you whether you would like to move these issues to a different version.</p>

The options discussed in the preceding table can be seen in the following screenshot:

Versions

Merge

For software projects, JIRA allows you to track different versions, e.g. 1.0, 2.0. Issues can be assigned to versions.

Name	Description	Start date	Release date	
<input type="text"/> Add				
2.0				
1.1			12/Jul/16	<input type="button" value="..."/>
1.0		01/Jul/16		<input type="button" value="Release"/> <input type="button" value="Archive"/> <input type="button" value="Delete"/>

Tip

There is also a Merge versions feature that allows you to merge multiple versions together. Merging versions will move issues from one version to another.

Other tabs

There are a number of other tabs on the **Project Administration** interface. We will not explore these tabs in detail, as they will each be covered in their own chapters later. We will, however, take a look at what each tab does, as shown in the following table:

Tab	Description
Issue types	This controls the types of issues that users can create for the project. For example, this may include Bugs , Improvements , and Tasks . Issue Types will be covered in Chapter 4, Issue Management .
Workflows	This controls the workflow issues that we will go through. Workflows consist of a series of steps that usually mimic the existing processes that are in place for the organization. Workflows will be covered in Chapter 7, Workflows and Business Processes .
Screens	Screens are what users see when they view, create, and edit issues in JIRA. Screens will be covered in Chapter 6, Screen Management .
Fields	These are what JIRA uses to capture data from users when they create issues. JIRA comes with a set of default fields and the JIRA administrator is able to add additional fields as needed. Fields will be covered in Chapter 5, Field Management .
Users and roles	Project administrators can define roles in the project and assign users to them. These roles can then be used to control permissions and notifications. Roles will be covered in Chapter 9, Securing JIRA .
Permissions	As we have already seen, permissions define who can perform certain tasks or have access in JIRA. Permissions will be covered in Chapter 9, Securing JIRA .
	JIRA allows users to control who can view the issues they created by selecting

Issue Security	<p>the issue security level.</p> <p>Issue security will be covered in Chapter 9, Securing JIRA.</p>
Notifications	<p>JIRA has the ability to send out e-mail notifications when certain events occur. For example, when an issue is updated, JIRA can send out an e-mail to alert all users who participate about the issue of the change.</p> <p>Notifications will be covered in Chapter 8, E-mails and Notifications.</p>

Importing data into JIRA

JIRA supports importing data directly from many popular issue-tracking systems, such as Bugzilla, GitHub, and Trac. All the importers have a wizard-driven interface, guiding you through a series of steps. These steps are mostly identical but have a few differences. Generally speaking, there are four steps when importing data into JIRA as follows:

1. Select your source data. For example, if you are importing from CSV, it will select a CSV file. If you are importing from Bugzilla, it will provide Bugzilla database details.
2. Select a destination project where the imported issues will go. This can be an existing project or a new project created on-the-fly.
3. Map old system fields to JIRA fields.
4. Map old system field values to JIRA field values. This is usually required for select-based fields, such as the priority field, or select list custom fields.

Importing data through CSV

JIRA comes with a CSV importer, which lets you import data in the comma-separated value format. This is a useful tool if you want to import data from a system that is not directly supported by JIRA, since most systems are able to export their data in CSV.

Tip

You are recommended to do a trial import on a test instance first.

Use the following steps to import data through a CSV file:

1. Select the **Import External Project** option from the **Projects** drop-down menu.
2. Click on the **CSV** importer option. This will start the import wizard.
3. First, you need to select a CSV file, which contains the data you want to import, by clicking on the **Choose File** button.
4. After you have selected the source file, you can also expand the **Advanced** section to select the file encoding and delimiter used in the CSV file. There is also a **Use an existing configuration** option, which we will talk about this later in this section.
5. Click on the **Next** button to proceed.

CSV File import

File import Setup Fields Values

File import

You are about to start the CSV import. To learn more about it, please see our [CSV importer documentation](#).

CSV Source File * No file chosen

The maximum file upload size is 10.00 MB. You can change this in [Attachments](#).

Use an existing configuration file

If you have used this importer before, you may have saved the configuration you used.

You can use that configuration again to save time.

File encoding *

CSV Delimiter

Leave blank for comma or enter '\t' for tab-delimited.

To include a delimiter character, place the value between double quotes.

To include a delimiter or a double quote character, place each value between double quotes.

Passwords will not be imported. Users will have to create new password when they first attempt to login.

6. For the second step, you need to select the project you want to import our data into. You can also select the **Create New** option to create a new project on-the-fly.
7. If your CSV file contains date-related data, ensure that you enter the format used in the **Date format** field.
8. Click on the **Next** button to proceed.

Map projects

File import Setup Fields Values

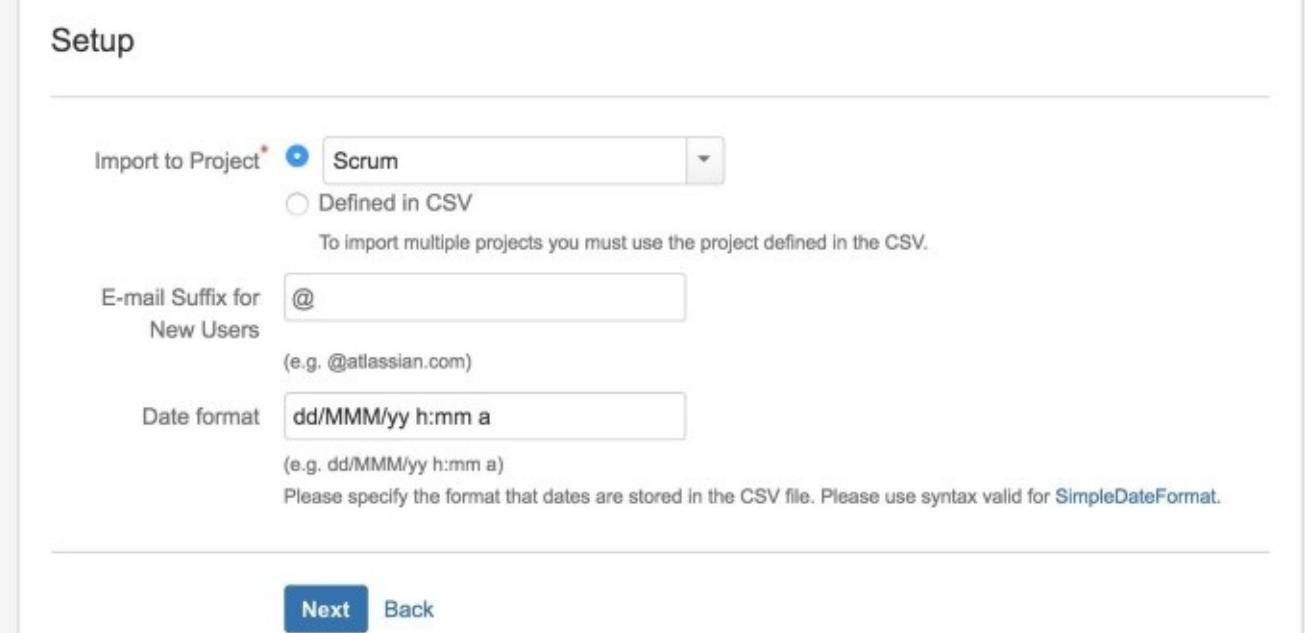

Setup

Import to Project * Scrum Defined in CSV
To import multiple projects you must use the project defined in the CSV.

E-mail Suffix for New Users
(e.g. @atlassian.com)

Date format
(e.g. dd/MMM/yy h:mm a)
Please specify the format that dates are stored in the CSV file. Please use syntax valid for `SimpleDateFormat`.

Next **Back**

9. For the third step, you need to map the CSV fields to the fields in JIRA. Not all fields need to be mapped. If you do not want to import a particular field, simply leave it as **Don't map this field** for the corresponding JIRA field selection.
10. For fields that contain data that needs to be mapped manually, such as for select list fields, you need to check the **Map field value** option. This will let you map the CSV field value to the JIRA field value, so they can be imported correctly. If you do not manually map these values, they will be copied over as-is.
11. Click on the **Next** button to proceed.

Map fields

File Import Setup Fields Values

Fields

Select the CSV fields to import, then set how you would like these converted to fields in JIRA. You can optionally map field values on the next screen.

CSV Field	JIRA field	Map field value
Issue Type (e.g. Story)	→ Issue Type	<input checked="" type="checkbox"/>
Priority (e.g. Medium)	→ Priority	<input checked="" type="checkbox"/>
Status (e.g. In Progress)	→ Status	<input checked="" type="checkbox"/>
Summary (e.g. As a scrum master, I can see the progress of a ...)	→ Summary	<input type="checkbox"/>

Working with multiples

For issues with multiple attachments, versions, components or comments use multiple columns in your CSV file. Use either: Different column names like Attachment 1, Attachment 2 then map each column to a corresponding JIRA field, or use the same column name (they will be mapped to the selected field).

Custom fields

Existing custom fields must be global to all projects.

Sub-tasks

To import issues as sub-tasks define the column mapping for: Issue Id, Parent Id and Issue Type

[Next](#) [Back](#)

12. For the last step, you need to map the CSV field value to the JIRA field value. This step is only required if you have checked the **Map field value** option for a field in step 10.
13. Enter the JIRA field value for each CSV field value.
14. Once you are done with mapping field values, click on the **Begin Import** button to start the actual import process. Depending on the size of your data, this may take some time to complete.

Map values

File Import Setup Fields Values

Values

CSV Field	Value from importer	Target value in JIRA
Issue Type (imported as issuetype)	Bug	→ Bug
	Epic	→ Epic
	Story	→ Story
	Sub-task	→ Sub-task
Priority (imported as priority)	Medium	→ Medium
Status (imported as status)	Done	→ Done
	In Progress	→ In Progress
	In Review	→ Done
	To Do	→ To Do

[Begin Import](#) [Back](#)

- Once the import process completes, you will get a confirmation message that tells you the number of issues that have been imported. This number should match the number of records you have in the CSV file.

1 projects and 23 issues imported successfully!

What now?

You can [download a detailed log](#) of this import. You can also [save the configuration](#) for future use.

[Import another project.](#)

On the last confirmation screen, you can click on the **download a detailed log** link to download the full log file containing all the information for the import process. This is particularly useful if the import was not successful.

You can also click on the **save the configuration** link, which will generate a text file containing all the mappings you have done for this import. If you need to run a similar import in the future, you can even use this import file so that you will not need to manually remap everything again. To use this configuration file, check the **Use an existing configuration file** option in step 4.

As we can see, JIRA's project importer makes importing data from other systems simple and straightforward. However, you must not underestimate its complexity. For any data migration, especially if you are moving off one platform and onto a new one, such as JIRA, there are a number of factors you need to consider and prepare for. The following list summarizes some of the common tasks for most data migrations:

- Evaluate the size and impact. This includes how many records you will be importing and also the number of users that will be impacted by this.
- Perform a full gap analysis between the old system and JIRA; for example, consider how the fields will map from one to the other.
- Set up test environments for you to run test imports on to make sure that you have your mappings done correctly.
- Involve your end users as early as possible and have them review your test results.
- Prepare and communicate any outages and support procedures post-migration.

The HR project

Now that we have seen all the key aspects that make up a project, let's revisit what you learned so far and put it to practice. In this exercise, we will set up a project for our Human Resource (HR) team to better track and manage employees joining and leaving the company as well as tasks related to the recruitment process.

Creating a new project

We will first start by creating a new project for the HR team. To create the project, perform the following steps:

1. Bring up the **Create project** dialog by selecting the **Create project** option from the **Projects** drop-down menu.
2. Select the **Task management** project template. We can use other templates in the **Business** project type; the task management template is the simplest option and will make future customization easier.
3. Name our new project as **Human Resource** and accept the other default values for **Key** and **Project Lead**.
4. Click on the **Submit** button to create the new project.

You should now be taken to the project browser interface for the new project.

Creating new components

Now with our new project in place, we need to go ahead and create a few components. These components will serve as groupings for our tasks. You need to perform the following steps to create our new components:

1. Click on the **Project administration** option in the bottom-left corner.
2. From the **Project Administration** interface, select the **Components** tab.
3. Enter Employee Onboarding for the new component's name.
4. Provide a short description for the new component.
5. Select a user to be the lead of the component.
6. Click on **Add** to create the new component.
7. Add a few more components.

With projects created as **Business** project type, components are not displayed by default, so we will have to manually add the **Components** field to the appropriate screens. We will cover fields and screens in [Chapter 5, Field Management](#), and [Chapter 6, Screen Management](#), respectively. For now, you need to perform the following steps to get our components to display when we create, edit, and view tasks.

1. From the **Project Administration** interface, select the **Screens** tab. There should be three screens, as shown in the following screenshot:

The screenshot shows the 'Screens' tab in the Project Administration interface. The title is 'HR: Task Management Issue Type Screen Scheme'. A description states: 'Screens allow you to arrange the fields to be displayed for an issue. Different screens can be used when an issue is created, viewed, edited, or transitioned through a workflow.' It notes that the screen scheme defines which screens apply to this project and allows changing the scheme. A message says 'This project uses only 1 screen scheme.' Below this, a section titled 'These 2 issue types... ...use this screen scheme' lists 'Task' (selected) and 'Sub-task'. A table maps operations to screens:

Operation	Screen
Create Issue	HR: Task Management Create Issue Screen
Edit Issue	HR: Task Management Edit/View Issue Screen
View Issue	HR: Task Management Edit/View Issue Screen

2. Click on **HR: Task Management Create Issue Screen**. This will open the **Configure Screen** page, with a list of fields that are currently on the selected screen.
3. Enter and select Component/s in the select field in the bottom of the page; this will add

the **Components** field onto the screen.

4. Repeat steps 2 and 3 for **HR: Task Management Edit/View Screen**.

Putting it together

Now that you have fully prepared your project, let's see how everything comes together by creating an issue.

1. Click on the **Create** button from the top navigation bar. This will bring up the **Create Issue** dialog box.
2. Select **Human Resource** for **Project** and **Task** for **Issue Type**.
3. Fill in the fields with some dummy data. Note that the **Components** field should display the components we just created.
4. Click on the **Create** button to create the issue.

If everything is done correctly, you should see a dialog box similar to the following screenshot, where you can choose your new project to create the issue in and also the new components that are available for selection:

The screenshot shows the 'Create Issue' dialog box. At the top right is a 'Configure Fields' button. Below the title 'Create Issue' is a toolbar with various icons. The main area has a large text input field with a placeholder 'What happened?'. Below it are sections for 'Assignee' (set to 'Automatic'), 'Priority' (set to 'Medium'), 'Labels' (empty), and 'Component/s' (a dropdown menu). The 'Component/s' dropdown contains three items: 'Employee Leaving', 'Employee Onboarding' (which is highlighted with a blue background), and 'Interview'. At the bottom right are 'Create' and 'Cancel' buttons.

You can test out the default assignee feature by leaving the **Assignee** field as **Automatic** and selecting a component; JIRA will automatically assign the issue to the default assignee defined for the component. If everything goes well, the issue will be created in the new project.

Summary

In this chapter, we looked at one of the most important concepts in JIRA, projects, and how to create and manage them. Permissions were introduced for the first time, and we looked at three permissions that are related to creating and deleting, administering, and browsing projects.

We were introduced to the two interfaces JIRA provides for project administrators and everyday users; the **Project Administration** interface and **Project Browser** interface, respectively. In the next chapter, we will look at projects created using the Software project type, namely for Scrum and Kanban to run agile projects.

Chapter 3. Using JIRA for Agile Projects

In the previous chapter, we looked at using JIRA for normal business projects, a feature that is provided by JIRA Core and is also available in JIRA Software. In this chapter, we will focus on the two project templates that are exclusive to JIRA Software, which are called Scrum and Kanban. We will take a brief overview of each of the agile methodologies, and look at how you can use JIRA for both.

By the end of this chapter, you will have learned the following:

- JIRA Software project templates
- How to run a project using JIRA's Scrum support
- Estimating work with Scrum
- How to run a project using JIRA's Kanban support
- Identifying inefficiencies in your process with Kanban
- Customizing your Scrum and Kanban boards

Scrum and Kanban

Scrum and Kanban are the two agile software development methodologies that have been supported in JIRA through an add-on called JIRA Agile. Starting with JIRA 7, Atlassian has added this support into their JIRA Software offering, making agile support a first-class citizen in the product.

If you are already familiar with Scrum and Kanban, feel free to skip this section. However, if you come from a more traditional waterfall model and are new to the agile movement, then here is an overview of them both. I would strongly recommend that you pick up an additional resource to learn more about each of the methodologies. A good place to start is the Kanban Scrum minibook, <https://www.infoq.com/minibooks/kanban-scrum-minibook>.

Scrum

Scrum is different to the waterfall model, in that it prescribes the notion of iteration. With Scrum, a project is divided into a number of iterations, called **sprints**, each lasting between two to four weeks, with the goal of producing a fully tested and potentially shippable product at the end.

At the beginning of each sprint, the product owner and the team come together in what is called a sprint-planning meeting. In this meeting, the scope of the next sprint is decided. This usually includes top priority items from the backlog, which contains all incomplete work.

During each sprint, the team meets on a daily basis to review progress and flag any potential problems or impediments and plans how to address them. These meetings are short, and the goal here is to make sure that everyone on the team is on the same page.

At the end of the sprint, the team will come together to review the outcome of the sprint and look at the things they did right and things that did not go well. The goal is to identify areas of improvement, which will feed into future sprints. The process continues until the project is completed.

Kanban

Kanban, unlike Scrum, which runs in iterations, focuses more on the actual execution of delivery. It has a heavy emphasis on visualizing the delivery workflow from start to finish, places limits on different stages of the workflow by controlling how many work items are allowed to be in each stage, and measures the lead time.

With Kanban, the importance is to be able to visually see the work items going through the workflow, identify areas of inefficiency and bottlenecks, and correct them. It is a continuous process with work coming in from one end, and going out from the other, and making sure that things go through as efficiently as possible.

Running a project with Scrum

As we have seen, JIRA comes with a number of project types, depending on what applications you have installed. The business project type, being part of JIRA Core, is available to all installations.

Business projects are very similar to how JIRA worked before JIRA 7, where it works as a highly customizable, generic task tracking system. The focus of business project type and its templates is for users to be able to easily create tasks and track and report on their progress.

Out of the box, you have three built-in templates, each with a set of predefined configurations, such as **workflows** and **fields**, to give you some idea on how to set up your projects. You can use them as is or customize them further based on your needs.

Creating a Scrum project

The first step to work with Scrum in JIRA is to create a project with the Scrum template:

1. Select the **Create project** option from the **Projects** drop-down menu.
2. Choose the **Scrum software development** template and click on **Next**.
3. Accept the settings and click on **Next**.
4. Enter the name and key for the new project and click on **Submit**:

Create project

Plan, track and report on all of your work within a project.
-  **Task management**
Quickly organize and assign simple tasks for you and your team.
-  **Process management**
Track all the work activity as it transitions through a streamlined process.

[Import a project](#) | [Create with shared configuration](#)

[Next](#) [Cancel](#)

Once the new Scrum project is created, you will be taken to the **Scrum** interface, as shown in the following screenshot:

The screenshot shows the JIRA Scrum interface. The left sidebar has sections for 'Backlog', 'Active sprints', 'Reports', and 'Issues'. Under 'PROJECT SHORTCUTS', it says 'Add a link to useful information for your whole team to see.' and '+ Add link'. Below that is a 'Give feedback' section and 'Project administration'. The main area is titled 'Backlog' with '11 ISSUES'. It includes a 'Create Sprint' button. A specific issue, 'SCRUM-3', is highlighted. Its details are shown on the right: 'As a user, I can find important items on the board by using the customizable "Quick Filters" above >> Try clicking the "Only My Issues" Quick Filter above', 'Estimate: Unestimated', 'Epic: None', 'People: Reporter: Patrick Li, Assignee: John Kennedy', and 'Dates: Created: 10 Jul '16 9:09 PM, Updated: 10 Jul '16 9:09 PM'. There are no linked issues.

The **Scrum** interface has the following main sections:

- **Backlog:** This is where all unplanned issues are stored. You can think of it as a to-do list. The product owner and the development team will work together to define the priorities of issues in the backlog, which will then be scheduled into sprints for delivery.
- **Active sprints:** This view shows the sprints that are currently underway and the issues that are part of the sprints. This is what the development team will use on a day-to-day basis to track their progress.
- **Reports:** This view contains a number of use report you can generate based on your team's performance. These reports help you and your team to visualize how the project is progressing and provide valuable feedback that you can use in future sprint planning sessions for improvements.

Working with the backlog

The backlog is the to-do list of your project where you keep all of your incomplete features (usually represented as stories). When you first start, you may have an empty backlog, so the first step is for the product owner and the team to work together to populate it with stories and tasks to be completed. During this activity, it works more like a brainstorming session, where the team works together to translate requirements from customers and other stakeholders into actionable stories and tasks.

Prioritizing and estimating work

Once you have the backlog populated, the next step is to estimate and prioritize the issues, so you can plan and build a schedule on how to complete them. In JIRA, prioritizing issues in the backlog means moving them up and down in the backlog by dragging and dropping. So to increase the priority of an issue, you can simply drag it higher in the backlog list. While this is usually the product owner's responsibility to prioritize what features to deliver first, the team should also be involved in this process to make sure that everyone is in sync on the direction.

Estimating work is a critical part of Scrum, and the success of your sprints heavily depends on how well you and your team can estimate. One thing people often get confused with is that they tend to think of estimation in terms of time; for example, story A will take five hours to complete. While this may seem right at first, what would often end up happening is people will either work extra hard in order to make the estimate seem accurate or give big estimates because they are uncomfortable with the task at hand. This can lead to big problems as the project goes on.

One way to avoid this pitfall is to use something arbitrary for estimation called story points, and this is the default estimation method in JIRA. The idea behind this is to measure and estimate issues based on their complexity, rather than time required to complete them. So, if you start a sprint with a total of 10 story points worth of issues, and at the end of the sprint, you are not able to complete all of them, this might indicate that you have been too aggressive and may need to reduce your expectations. Since the estimation is not done based on the time taken, it simply indicates that perhaps the issues are too complex, and you will need to break them down further into more digestible pieces. This helps to avoid people feeling they are running against the clock, and also help you to better define and break down tasks into a smaller, more manageable size.

Sometimes, however, you might find it difficult to estimate the complexity of your stories. This is usually a sign that you either do not have enough information about the story, or the story's scope is too big can needs to be broken down. It is important for the team and to realize this and not shy away from going back to ask more questions in order to fully understand the purpose of the story before providing an estimate.

Now that we have determined a way to estimate our issues, to enter the estimate is as simple as

doing the following:

1. Select the issue to estimate from the backlog.
2. Enter the number of story points into the **Estimate** field, as shown in the following screenshot:

The screenshot shows a Jira issue card for an issue titled "SCRUM / SCRUM-2". The card has a sidebar on the left with icons for attachments, info, comments, attachments, and a checklist. The main content area starts with a tip message: "As a team, I'd like to commit to a set of stories to be completed in a sprint (or iteration) >> Click "Create Sprint" then drag the footer down to select issues for a sprint (you can't start a sprint at the moment because one is already active)". Below this, the "Estimate" field is highlighted with a blue border and contains the value "5". The "Details" section follows, containing fields for Status (IN PROGRESS), Component/s (None), Labels (None), Affects Version/s (None), Fix Version/s (None), and Epic (None). The "IN PROGRESS" status is highlighted with a yellow background.

Field	Value
Status	IN PROGRESS
Component/s	None
Labels	None
Affects Version/s	None
Fix Version/s	None
Epic	None

Tip

You should not change the estimate once the issue is added to an active sprint, as this is generally discouraged. Changing estimate mid-sprint can lead to bad estimation during the spring planning phase and future improvements.

Creating a new sprint

With the backlog populated and issues estimated, the next step is to create a sprint for the team to start working on. To create a new sprint, perform the following steps:

1. Go to the backlog of your project.
2. Click on the **Start Sprint** button. This will create a new empty sprint.
3. Add issues to the sprint by dragging and dropping issues into the sprint box, as shown in the following screenshot:

The screenshot shows a Jira backlog interface. On the left, there's a sidebar with a 'EPICS' section. The main area has two sections: 'SCRUM Sprint 2' (0 issues) and 'Backlog' (5 issues). The 'SCRUM Sprint 2' section contains a green dashed box labeled 'Plan a sprint by dragging the sprint footer down below some issues, or by dragging issues here'. Inside this box is an issue titled 'SCRUM-2 As a team, I'd like to commit to a set of stories to be completed in a sprint (or iteration) >> Click "Create Sprint" then...'. Below the sprint box are buttons for 'Start Sprint' and 'Estimate 0'. The 'Backlog' section contains five issues: 'SCRUM-9', 'SCRUM-17', 'SCRUM-20', and 'SCRUM-21', each with a brief description and a 'Create Sprint' button. The bottom right of the backlog section has a 'Create Sprint' button.

Once the team has decided on the scope, it is time to start the sprint:

1. Click on the **Create Sprint** button.
2. Select the duration of the sprint. Generally speaking, you would want to keep your sprint short. Between one to two weeks is usually a good length.
3. Click on the **Start** button to start your sprint.

Once the sprint is started, you can go to the active sprints view and the team can start working on delivery.

Start Sprint

5 issues will be included in this sprint.

Sprint Name: * SCRUM Sprint 2

Duration: * 2 weeks

Start Date: * 01/Aug/16 10:10 PM 

End Date: * 15/Aug/16 10:10 PM 

There are 10 working days in this sprint [\(?\) More about working days](#)

Note

If the **Start Sprint** button is greyed out, it means you already have an active sprint running and do not have the **parallel sprints** option enabled.

Normally, you will only have one team working on the project at any given time, but if you have a big team, and people will work on different part of the project at the same time, you need to enable the parallel sprints option:

1. Log in to JIRA as an administrator.
2. Browse to the JIRA administration console.
3. Select the **Applications** tab and then **JIRA Software configuration**.
4. Check the **Parallel Sprints** option to enable it.

With the parallel sprints option enabled, you can start multiple sprints at the same time. When running multiple sprints, it is best to keep them separate from each other, so they do not get into each other's way. A good example will be two sprints focusing on different areas of the project, such as delivery and documentation.

In JIRA, when you have parallel sprints, the active sprint view will only show one sprint at a

time, so you will need to toggle between the sprints, as shown in the following screenshot:

The screenshot shows a Scrum board interface with the following details:

- Header:** SCRUM board, All sprints, Switch sprint ▾, Board ▾, and a refresh icon.
- Quick Filters:** Documentation Sprint, Recently Updated, and Development Sprint (which is highlighted with a red box).
- Columns:** To Do, In Progress, and Done.
- Issues:**
 - John Kennedy:** 2 issues
 - SCRUM-3: As a user, I can find important items on the board by using the customisable "Quick Filters".
 - SCRUM-19: As an Agile team, I'd like to learn about Scrum >> Click the "SSP-1" link at the left of this row to
 - Kim Lee:** 2 issues
 - SCRUM-4: As a developer, I can update story and task status with drag and drop (click the triangle at far
 - SCRUM-1: As a scrum master, I can see the progress of a sprint via the Burndown Chart >> Click

Running through a sprint

Once the team has prioritized the issues and started a sprint during the sprint-planning meeting, the agile board will switch over to the active sprint view. For normal teams, you will have one active sprint at any given time, and your Scrum board will look as shown in the following screenshot:

The screenshot shows a Jira Scrum board titled "SCRUM Sprint 1". The board has three columns: "To Do", "In Progress", and "Done".

- To Do:** Contains 2 issues assigned to John Kennedy:
 - SCRUM-3: As a user, I can find important items on the board by using [smiley face]
 - SCRUM-19: As an Agile team, I'd like to learn about Scrum >> [purple profile]
- In Progress:** Contains 2 issues assigned to Kim Lee:
 - SCRUM-4: As a developer, I can update story and task status with [red profile]
 - SCRUM-1: As a scrum master, I can see the progress of a sprint [orange profile]
- Done:** Contains 2 issues assigned to Tom Johnson:
 - SCRUM-8: As a team, we can finish the sprint by clicking the cog [blue profile]
 - SCRUM-18: As a product owner, I'd like to express work in terms of [blue profile]

A sidebar on the right shows the details for SCRUM-18, including its description: "As a product owner, I'd like to express work in terms of actual user problems, aka User Stories, and place them in the backlog >> Try creating a new story with the '+ Create Issue' button (top right of screen)". It also shows the estimate as "Unestimated". The sidebar includes sections for Details, Status (IN PROGRESS), Component/s (None), Labels (None), Affects Version/s (None), Fix Version/s (None), and Epic (None).

The Scrum board is made up of vertical columns that represent various states an issue can be in, and they are mapped to the workflow used by the project. So in our example, we have the default workflow with three states, **To Do**, **In Progress**, and **Done**. As we will see later, the project administrator will be able to customize this.

The board can also be divided into a number of horizontal rows called swimlanes. These help you to group similar issues and make your board easier to understand. For example, we are grouping issues into swimlanes based on the issue assignee in our example. Just like columns, the project administrator can customize how swimlanes should be defined.

On the Scrum board, each issue is represented as a card, and developers can drag them across the board as they work through them.

When a sprint is underway, it is important to avoid introducing scope creep by adding more issues to the sprint, and it falls on the Scrum master and the product owner to make sure that the team is not distracted or blocked by any impediments. However, from time to time, emergency situations that demand certain features or fixes need to be included do arise, and in these cases, you can add new issues into the active sprint from the backlog view.

Do keep in mind though, that this should not become a common habit, as it is very distractive, and it is usually a sign of bad sprint planning or poor communication with stakeholders. JIRA will also prompt you whenever you try to add more issues to an active sprint:

The screenshot shows the JIRA SCRUM board interface. On the left, there's a sidebar with icons for User, Versions, Stories, and EPICS. The main area is titled 'SCRUM board' and 'Backlog'. At the top, there are 'QUICK FILTERS' for 'Only My Issues' and 'Recently Updated'. A date range from '01/Aug/10 0:13 PM' to '10/Aug/10 0:13 PM' is shown. A modal dialog box is open, titled 'Move issue'. It contains a yellow warning box with the text 'Sprint scope will be affected by this action.' Below this, it says 'SCRUM-21 will be moved from the backlog to sprint SCRUM Sprint 1.' At the bottom of the dialog are 'Confirm' and 'Cancel' buttons. In the background, the backlog list shows several items starting with 'SCRUM-21'. At the bottom right of the main screen, there's a 'Create' button.

At the end of the sprint, you need to complete the sprint by doing the following:

1. Go to the Scrum board and click on **Active sprints**.
2. Click on the **Complete Sprint** link.

The screenshot shows a confirmation dialog titled 'Complete Sprint: SCRUM Sprint 1'. Inside, it says '1 issue was done' and '5 issues were incomplete'. It also states 'Incomplete issues will be moved to the backlog'. A note at the bottom says 'Sub-tasks are not included in the total(s) above, and are always included in the same sprint as their parent issue.' At the bottom right are 'Complete' and 'Cancel' buttons.

3. Click on the **Complete** button to finish the sprint.

Once you have completed a sprint in JIRA, any unfinished issues will be placed back into the backlog. Sometimes, you may have other sprints planned but not active; in this case, issues that are not completed from the current active sprint can be automatically added to the next available sprint.

It can be tempting to extend the sprint for just a few more days because you have just one more issue to complete. While this is not a hard rule, generally you should avoid this and just let the incomplete issue go back to the backlog and reprioritize it during the next sprint meeting. This is because Scrum is an iterative process and the goal is not to make everyone work as hard as possible, but to be able to retrospectively look at what the team did right and/or wrong in the previous sprint and address that in the next sprint. Perhaps the reason is due to inaccurate estimation or incorrect assumptions made during requirement gathering. The point here is the team should view this as an opportunity to improve rather than a failure to be rushed. Simply extending the current sprint to accommodate incomplete items can turn into a slippery slope where the practice becomes the norm, and the root problem is masked.

Running a project with Kanban

Now that we have seen how to run projects with Scrum, it is time to take a look at the other agile methodology JIRA Software supports—Kanban. Compared to Scrum, Kanban is a much simpler methodology. Unlike Scrum, which has a backlog and requires the team to prioritize and plan their delivery in sprints, Kanban focuses purely on the execution and measurement of throughput.

In JIRA, a typical Kanban board will have the following differences compared to a Scrum board:

- There is no backlog view. Since Kanban does not have a sprint-planning phase, your board acts as the backlog.
- There are not active sprints. The idea behind Kanban is that you have a continuous flow of work.
- Columns can have minimum and maximum constraints.
- Columns will be highlighted if the constraints are violated. As shown in the following screenshot, both the **Selected for Development** and **In Progress** columns are highlighted due to constraint violation:

The screenshot shows a JIRA Kanban board titled "Kanban board". At the top, there are quick filters: "Only My Issues" and "Recently Updated". Below the filters, there are five columns with the following counts: "8 Backlog", "2 Selected for Development", "6 In Progress Max 5", "8 Done Max 15", and "Release...". A horizontal bar indicates the current count in each column: yellow for "Selected for Development" (2) and red for "In Progress" (6). Under the "Selected for Development" column, there is a section for "Catherine" with 2 issues. One issue is KANBAN-16: "Develop responsive mobile client UI". Under the "In Progress" column, there is a section for "Jack" with 5 issues. One issue is KANBAN-8: "As a team, we can finish the sprint by clicking the cog icon next to the sprint". Another issue is KANBAN-5: "SSP-10 When the last task is done, the story can be automatically closed". Both the "Selected for Development" and "In Progress" columns are highlighted with yellow and red respectively, indicating constraint violations.

Creating a Kanban project

The first step to work with Kanban in JIRA is to create a project with the Kanban template:

1. Select the **Create project** option from the **Projects** drop-down menu.
2. Choose the **Kanban software development** template and click on **Next**:

The screenshot shows the 'Create project' dialog in JIRA. At the top, there's a 'Create project' button and a 'View Marketplace Workflows' link. Below that, there are two main sections: 'SOFTWARE' and 'BUSINESS'. Under 'SOFTWARE', there are two options: 'Scrum software development' (described as Agile development with a board, sprints and stories) and 'Kanban software development' (described as Optimise development flow with a board. Connects with source and build tools). The 'Kanban software development' option is highlighted with a blue background and a callout box. Under 'BUSINESS', there are two options: 'Project management' (described as Plan, track and report on all of your work within a project) and 'Task management' (described as Quickly organize and assign simple tasks for you and your team). At the bottom, there are links for 'Import a project' and 'Create with shared configuration', and buttons for 'Next' and 'Cancel'.

3. Accept the settings and click on **Next**.
4. Enter the name and key for the new project and click on **Submit**.

After you have created a Kanban project, you will be taken to the Kanban board view, which looks very similar to the active sprint view of a Scrum board. Remember, with Kanban, it is like you are running a sprint that does not end or ends when the entire project is completed. So the agile board itself focuses on helping you and your team to execute on delivery.

Using the Kanban board

As we have mentioned earlier, with Kanban, there is no planning phase, so you go straight to the issues board. Working with the Kanban board is actually very simple; new issues created by you and your team go straight onto the board and into the first column, called **Backlog** by default.

Members of the team will then grab issues from the Backlog column, assign the issue to them, and move them through the workflow. During various stages, issues may need to be re-assigned to other users, for example, when an issue leaves the development stage and enters testing, it may be re-assigned to a test engineer. Once enough issues have been completed (moved to the last column, called **Done** by default), a release can be made. Once released, all issues in the **Done** column will be removed from the board (still in the system), so the team can continue to focus on the tasks at hand.

Let's look at an example of the Kanban board shown in the following screenshot, in which we can clearly see that we have problems in both the **In Development** and **In Testing** phases of our process. **In Development** is highlighted in red, meaning we have enough work there, which is a sign of bottleneck. **In Testing** is highlighted in yellow, which means that we do not enough work and is a sign of efficiency:

The screenshot shows a Kanban board interface with the following details:

- QUICK FILTERS:** Only My Issues, Recently Updated
- Columns:**
 - Backlog:** 8 issues
 - In Development:** 6 issues (highlighted in red)
 - In Testing:** 2 issues (highlighted in yellow)
 - Done:** 8 issues
- Issues in the In Development column:**
 - KANBAN-16: Develop responsive mobile client UI
 - KANBAN-15: As an Agile team, I'd like to learn about Scrum >> Click the "SSP-1" link at [link]
- Issues in the In Testing column:**
 - KANBAN-9: As a team, I'd like to estimate the effort of a story in Story Points so [link]
 - KANBAN-8: As a team, we can finish the sprint by clicking the cog icon next to the [link]
 - KANBAN-5: SSP-10 When the last task is done, the story can be automatically [link]
 - KANBAN-10: As a product owner, I'd like to rank stories in the backlog so I can [link]
 - KANBAN-11: As a team, I'd like to commit to a set of stories to be completed [link]
- Issues in the Done column:**
 - KANBAN-21: As a product owner, I'd like to include bugs, tasks and other issue [link]
 - KANBAN-3: As a user, I can find important items on the board by using the [link]
 - KANBAN-20: As an Agile team, I'd like to learn about Scrum >> Click the "SSP-1" link at [link]

With this, the board is able to visually tell us where we are having problems and allows us to focus on these problem areas. The bottleneck in the **In Development** phase could mean we do not have enough developers, which causes the efficiency in the **In Testing** phase, where our testers are simply sitting around waiting for work to come.

So, this raises a common question: what should be the correct constraints for my columns? The quick answer is, *try and experiment as you go*.

The long answer is, there is no single correct, silver bullet answer. What you need to understand is, there are many factors that can influence the throughput of your team, such as the size of your team, team member leaving and joining, as well as the tasks at hand. In our example, the easy solution will be to lower the limit for both columns and we are done. But often, it is just as important for you to find the root cause of the problem rather than trying to simply fix the board itself. Perhaps, what you should try to do is get more developers onto your team so you can keep up the pace that is required for delivery. The take away here is that the Kanban board can help you pinpoint areas of problem, and it is up to you and your team to figure out the cause and find the appropriate solution.

Configuring agile boards

Now that we have seen how to use JIRA Software to run both Scrum and Kanban projects, let's take a look at how to customize our agile board. Since JIRA Software is built on top of JIRA Core, many of its customization options leverage the core features of JIRA. So if you are not familiar with some of these features, such as workflows, do not worry, we will cover these in high level in context of agile board, and dive into the details of each in later chapters.

Configuration columns

For both Scrum and Kanban, the board's columns are mapped to the workflow used by the project and the default workflow created is very simple. For example, the default Scrum workflow contains three statuses: **To Do**, **In Progress**, and **Done**. However, this is often not enough, as projects will have additional steps in their development cycle, such as testing and review. To add new columns to your board, follow these steps:

1. Browse to your project's agile board.
2. Click on the **Board** menu and select the **Configure** option.
3. Select the **Columns** option from the left navigation panel.
4. Click on the **Add Column** button.
5. Enter the name for the new column and select its category. Generally speaking, your new column would fall into the **In Progress** category, unless you are replacing the **To Do** or **Done** column.
6. Drag and drop the new column to place it in the correct location within your development workflow.

For projects using the workflows created along with your new project (also known as **Simplified Workflow**), this is all you need to do to customize your columns. If you have an existing workflow and want to adapt your columns to that, we will cover workflows in [Chapter 7, Workflow and Business Process](#).

The screenshot shows the 'Configure SCRUM board' interface. On the left, a sidebar lists configuration options: General, Columns (which is selected and highlighted in blue), Swimlanes, Quick Filters, Card colors, Card layout, Estimation, Working days, and Issue Detail View. The main area is titled 'Column management' with a sub-instruction: 'Columns can be added, removed, reordered and renamed. Columns are based upon global statuses and can be moved between columns. Minimum and maximum constraints can be set for each mapped column.' A modal dialog box is open, titled 'Add column'. It contains fields for 'Name:' (set to 'In Review') and 'Category:' (set to 'In Progress'). Below these fields is a note: 'The category for the existing status with this name will be used'. At the bottom of the dialog are 'Add' and 'Cancel' buttons, along with 'Add status' and 'Add column' links. The main board area shows four columns: 'To Do', 'In Progress', and 'Done' (all in yellow), and an 'Unmapped Statuses' section. The 'To Do' column has 8 issues, the 'In Progress' column has 6 issues, and the 'Done' column has 9 issues. Each column has a 'Set resolution' checkbox. The 'Unmapped Statuses' section has a placeholder: 'Drag statuses from a column to unmap them.'

Setting up column constraints

In the previous Kanban section, we discussed that one of the key aspects of Kanban is to control the amount of work.

Tip

While work constraint is a concept used in Kanban, sometimes people also adopt it with Scrum. This allows you to use Scrum for planning and Kanban for execution in a hybrid methodology called **Scrumban**.

To set up column constraints for your agile board, perform these steps:

1. Browse to your project's agile board.
2. Click on the **Board** menu and select the **Configure** option.
3. Select the **Columns** option from the left navigation panel.
4. Select how you want constraint to be calculated in the **Column Constraint** option. By default, Kanban board will use the **Issue Count** option, while Scrum board will not have any constraint.
5. Enter the minimum and maximum value for each of the columns you want to apply constraint to.

You do not have to set both the minimum and maximum for a constraint. Consider our example shown in the following screenshot, where we have set the constraint for **Selected for Development** to be at least three issues and no more than 10 issues. For the **In Progress** column, we have only limited it to be no more than five issues, but there is no minimum value, meaning it can have no issues at all. We also placed a maximum limit of 15 issues for the **Done** column, so we can be alerted when the team has reached the threshold of completed issues and a release needs to be made:

Column management

Columns can be added, removed, reordered and renamed. Columns are based upon global statuses and can be moved between columns. Minimum and maximum constraints can be set for each mapped column.

The screenshot shows the 'Column management' section of the JIRA software. At the top, there's a dropdown menu for 'Column Constraint' set to 'Issue Count'. Below it, a note says 'Constraints can be added to columns on the board for one statistic.' Under 'Days in column', a checked checkbox indicates 'Show a visual indicator on each card that represents the time spent in the column. This can help identify slow moving issues.' In the 'Simplified Workflow' section, the heading 'Using Simplified Workflow' is followed by a note: 'The workflow for project Kanban is currently managed by JIRA Software. Project Administrators can add and remove statuses below.' Below this are two buttons: 'Add status' and 'Add column'. A table lists unmapped statuses: 'Backlog' (drag to rearrange or delete), 'Selected for Dev...' (drag to rearrange, or delete), 'In Progress' (drag to rearrange, or delete), and 'Done' (drag to rearrange, or delete). A note says 'Drag statuses from a column to unmap them'. Below the table, four columns represent the workflow: BACKLOG (8 issues, no resolution), SELECTED FOR DE... (2 issues, no resolution), IN PROGRESS (6 issues, no resolution), and DONE (8 issues, checked resolution). The 'IN PROGRESS' and 'Done' columns have red borders around their status boxes, indicating constraint violations.

After you have set the column constraints for your board, every time the rules are violated, JIRA will immediately alert you on your agile board. For example, in the following screenshot, we have two issues in the **Selected for Development** column, which has a minimum of three issues, so the column is highlighted in yellow. In the **In Progress** column, we have six issues, and since it has a maximum limit of five issues, the column is highlighted in red.

Note that while JIRA will highlight the columns when a constraint is violated, it does not actually stop you from breaking the constraints. It is simply a way to alert the team that something has gone wrong in the process and it needs to be reviewed and corrected:

Kanban board

QUICK FILTERS: Only My Issues Recently Updated

8 Backlog**2** Selected for Development

Min 3 Max 10

6 In Progress Max 5**8** Done Max 15

Release...

 As a developer, I can update story and task status with drag and drop.	 As a team, we can finish the sprint by clicking the cog icon next to the story.	 As a scrum master, I can see the progress of a sprint via the board.	 As a product owner, I'd like to rank stories in the backlog so I can prioritize them.
 KANBAN-7 As a developer, I can update details on an item using the Detail view.	 KANBAN-16 Develop responsive mobile client UI.	 KANBAN-2 As a team, I'd like to commit to a set of stories to be completed.	 KANBAN-11 As a team, I'd like to commit to a set of stories to be completed.
 KANBAN-9 As a team, I'd like to estimate the effort of a story in Story Points so I can prioritize it.		 KANBAN-3 As a user, I can find important items on the board by using the search function.	 KANBAN-12 As a team, I'd like to estimate the effort of a story in Story Points so I can prioritize it.
 KANBAN-18 As a scrum master, I'd like to break stories down into tasks we can track.		 KANBAN-5 SSP-10 When the last task is done, the story can be automatically closed.	 KANBAN-13 As a product owner, I'd like to rank stories in the backlog so I can prioritize them.
 KANBAN-19 As a product owner, I'd like to express work in terms of actual user stories.		 KANBAN-6 SSP-10 Update task status by dragging and dropping from column to column.	 KANBAN-14 As a product owner, I'd like to express work in terms of actual user stories.
 KANBAN-21		 KANBAN-20	 KANBAN-15

Configuring swimlanes

As we saw in earlier sections, JIRA's agile board lets you group similar issues together in horizontal rows called swimlanes. Unlike columns, which are mapped to workflow statuses, you can define swimlanes based on any criteria, including custom fields you have added yourself. To set up swimlanes for your board, you need to perform the following steps:

1. Browse to your project's agile board.
2. Click on the **Board** menu and select the **Configure** option.
3. Select the **Swimlanes** option from the left navigation panel.
4. Select how you want to define your swimlanes in the **Base Swimlanes on** field.
5. If you choose the **Queries** option, you will need to define the query for each swimlane you want to add to the board.

There are five options when choosing how swimlanes will be defined:

- **Queries:** Swimlanes will be based on the JQL queries you define. For each swimlane, you need to define the JQL query that will return the issues you want for the swimlane. Issues that match more than one query will only be included in the first swimlane. JQL will be covered in [Chapter 10, Searching, Reporting, and Analysis](#).
- **Stories:** Swimlanes will be based on user stories. Subtasks that belong to the same story will be displayed in the same swimlane.
- **Assignees:** Swimlane will be based on each issue's assignee. Issues with the same assignee will be grouped in the same swimlane. The sample Scrum board we have shown in the **Scrum** section uses this option.
- **Epics:** Swimlanes will be based on epics each issue belongs to. Issues in the same epic will be grouped into the same swimlane.
- **No Swimlanes:** The agile board will not be using swimlanes, all issues will be grouped together in one single row.

As shown in the following example, we are using the **Queries** option and we have defined two swimlanes (and the default **Everything Else** lane). For the JQL query, we are searching based on a custom field that we have created called **Source** to determine whether the feature request comes from a customer or as a result of an internal review. Custom fields will be covered in [Chapter 5, Field Management](#).

As you can see, there is lot flexibility when it comes to configuring your swimlanes, and with JQL, we can define any arbitrary rule for our swimlanes.

Swimlanes

A swimlane is a row on the board that can be used to group issues. Swimlane type can be changed below and will be saved automatically.
Note: queries will not be lost when changing to another swimlane type.

Base Swimlanes on

Queries

Group issues by custom queries. Queries are based on JQL that is additional to the saved filter of this board.

Name	JQL	Description	
	<input checked="" type="checkbox"/>		Add
Customer Requests	Source = Customer	Requests from customer.	Delete
Internal Requests	Source = "Internal Review"		Delete
Everything Else			

Defining quick filters

By default, your agile board will display all issues. For Scrum, it will be all issues in the sprint, and for Kanban, it will be all issues that have been released. This can be quite distracting when you want to hone in on specific issues, such as top priority ones. While swimlanes can help with that, having too many issues on the board can still be very "noisy".

One useful feature JIRA has is that you can create a number of predefined filters for your board. With these, you can quickly filter out the issues you do not care about and only have the issues that matter to you shown on the board. Note that this does mean the other issues are removed from the board, they are simply hidden from view.

JIRA already comes with two built-in quick filters, called **Only My Issues** and **Recently Updated**. You can create your own by following these steps:

1. Browse to your project's agile board.
2. Click on the **Board** menu and select the **Configure** option.
3. Select the **Quick Filters** option from the left navigation panel.
4. Enter a name for the new filter and the JQL query that will return the filtered issues.

In the following example, we are creating a new filter called **Customer Requests** and using the JQL to search for issues with Source field set to Customer:

The screenshot shows the 'Quick Filters' configuration page. At the top, there is a note: 'Quick Filters can be used to further filter the issues in the board based on the additional JQL query.' Below this, a table lists existing filters and allows for creating new ones. The columns are 'Name', 'JQL', and 'Description'. A modal window is open for creating a new filter named 'Customer Request'. In the 'JQL' field, the query 'Source = Customer' is entered with a checked checkbox. The 'Description' field is empty. Buttons for 'Update' and 'Cancel' are visible at the bottom of the modal. The table below contains three rows: 'Only My Issues' with JQL 'assignee = currentUser()' and description 'Displays issues which are currently assigned to the current user'; 'Recently Updated' with JQL 'updatedDate >= -1d' and description 'Displays issues which have been updated in the last day'; and the newly created 'Customer Request' filter.

Name	JQL	Description
Customer Request	Source = Customer	
Only My Issues	assignee = currentUser()	Displays issues which are currently assigned to the current user
Recently Updated	updatedDate >= -1d	Displays issues which have been updated in the last day

After you have added your new filter, it will be displayed next to the existing ones, ordered alphabetically. Clicking on the filter will immediately filter out the issues that do not fit the criteria. You can also chain filter the issues by selecting multiple filters, as shown in the following screenshot. We have enabled both **Customer Requests** and **Recently Updated**

filters to get a view on recently updated customer requests:

SCRUM board

All sprints [Switch sprint](#)

Board

QUICK FILTERS: [Customer Requests](#) [Only My Issues](#) [Recently Updated](#)

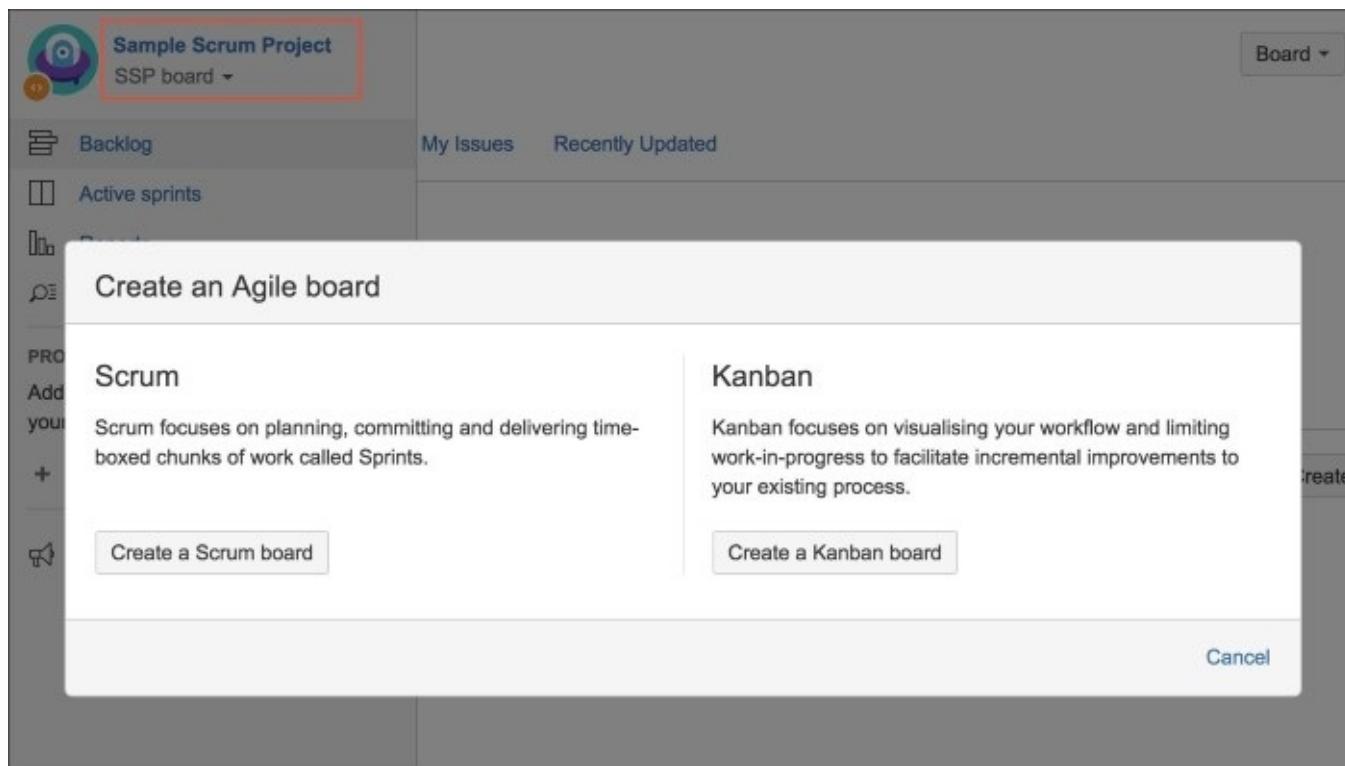

To Do	In Progress	Done
✓ John Kennedy 2 issues	<p> SCRUM-3 As a user, I can find important items on the board by using the customisable "Quick Filters" above</p>	<p> SCRUM-19 As an Agile team, I'd like to learn about Scrum >> Click the "SSP-1" link at the left of this row to see</p>
✓ Kim Lee 1 issue		
✓ Patrick Li 2 issues	<p> SCRUM-4 As a developer, I can update story and task status with drag and drop (click the triangle at far left of this</p>	<p> SCRUM-1 As a scrum master, I can see the progress of a sprint via the Burndown Chart >> Click "Reports"</p>
✓ Unassigned 1 issue	<p> SCRUM-20 As a product owner, I'd like to include bugs, tasks and other issue types in my backlog >> Bugs like</p>	

Creating new agile board for project

When you create a new project using the Scrum and Kanban project template as described earlier in this chapter, JIRA will automatically create an agile board for your project. Along with this default board, you can create additional boards for your project.

For example, if you created a Scrum project, and you have two teams working on the project. You can create a new Scrum board for the second team, so each team can work with their own agile boards and not get in each other way. Another example will be if your second team needs to run their part of the project using Kanban. You can easily add a new Kanban board to the Scrum project, so each team can use the agile methodology they want for the same project. To add a new agile board to your project:

1. Browse to your project's agile board.
2. Click the current board's name from the top left-hand corner, and select the **Create board** option.
3. Select the agile board type you want to create, and follow the onscreen wizard to create the new board:

Once the new agile board is created, it will be added to the agile boards menu from the top left hand corner, and you can switch between the boards by selecting the one you want.

Including multiple projects on a board

By default, when you create a new project, the agile board created will only include issues from the current project. This is usually fine if your project is self-contained. However, there might be cases where you have multiple projects that are related, or dependent on each other, and in order for you to get an overall picture, you need to have issues from all those projects shown on a single agile board.

The good news is, JIRA lets you do just this. One thing to understand here is, JIRA uses what is called a **filter** to define what issues will be included on the board. Filters are like saved search queries, and when a project is created, JIRA automatically creates a filter that includes all issues from the current project. This is why the default agile board created with the project will always display the project's issues only. Filters are discussed in [Chapter 10, Searching, Reporting, and Analysis](#).

So for you to include issues from other projects on the agile board, all you need to do is update the filter the board is using:

1. Browse to your project's agile board.
2. Click on the **Board** menu and select the **Configure** option.
3. Select the **General** option from the left navigation panel.
4. Click the **Edit Filter Query** link for **Saved Filter** option if you want to update the filter that is currently used by the board. Alternatively, if you already have a filter that has all the issues you want to include, you can hover over and click on the current filter, and select the new filter to use:

Note

Since filters need to be shared with users in order for them to see the issues they return, make sure your filter is shared with the same group of users as the board is set to. Generally, you can just share the filter with the project.

General and filter

The Board filter determines which issues appear on the board. It can be based on one or more projects, or custom JQL depending on your needs.

Summary

In this chapter, we introduced the software project templates that come with JIRA Software, and the two main agile methodologies it supports, namely Scrum and Kanban. We talked about how you can run projects in each of the methodologies using JIRA and the features it provides.

We also looked at some of the customization options available for you as the project owner, to configure the agile board to fit your needs. We looked at how to customize the board's columns to better adapt to your team's workflow and using swimlanes to group similar issues together. We also looked at how to create quick filters to easily filter out irrelevant issues from view, so we can focus on the issues that matter.

In the next chapter, we will look at **issues**, the key data you work with in your projects, and what you can do with them.

Chapter 4. Issue Management

In the previous chapter, you saw that JIRA is a very flexible and versatile tool that can be used in different organizations for different purposes. A software development organization will use JIRA to manage its software development lifecycle and for bug tracking, while a customer services organization may choose to use JIRA to track and log customer complaints and suggestions. For these reasons, issues in JIRA can represent anything that is applicable to real-world scenarios. Generally speaking, an issue in JIRA often represents a unit of work that can be acted upon by one or more people.

In this chapter, we will explore the basic and advanced features offered by JIRA for you to manage issues. By the end of this chapter, you will have learned the following:

- Issues and what they are in JIRA
- Creating, editing, and deleting issues
- Moving issues between projects
- Expressing your interest in issues through voting and watching
- Advanced issue operations, including uploading attachments and linking issues

Understanding issues

Depending on how you are using JIRA, an issue can represent different things and can even look very different in the user interface. For example, in JIRA Core, an issue will represent a task and will look like this:

The screenshot shows a JIRA Core issue page for a task titled "Send contract document for #CON_7829". The page includes a navigation bar with "Edit", "Comment", "Assign", "More", "Done", and "Admin" buttons. Below this is a "Details" section with the following information:

Type:	<input checked="" type="checkbox"/> Task	Status:	TO DO (View Workflow)
Priority:	↑ Medium	Resolution:	Unresolved
Affects Version/s:	None	Fix Version/s:	None
Component/s:	Review		
Labels:	None		

While in JIRA Software, if you are using the agile board, an issue can represent a story, or epic, and will resemble a card:

The screenshot shows a JIRA Software agile board card for an issue titled "SCRUM-3". The card has the status "In Progress". The description text on the card reads: "As a user, I can find important items on the board by using the customisable "Quick Filters" above >> Try clicking the "Only My Issues" Quick Filter above". To the right of the text is a placeholder profile picture.

Despite all the differences in what an issue can represent and how it might look, there are a number of key aspects that are common for all issues in JIRA, as follows:

- An issue must belong to a project.
- It must have a type, otherwise known as an issue type, which indicates what the issue is representing.
- It must have a summary. The summary acts like a one-line description of what the issue is about.
- It must have a status. A status indicates where along the workflow the issue is at a given time. We will discuss workflows in [Chapter 7, Workflows and Business Processes](#).

So in summary, an issue in JIRA represents a unit of work that can be completed by a user, such as a task in JIRA Core, a story in JIRA Software, or a request in JIRA Service Desk, are all different forms of an issue.

JIRA issue summary

As we have discussed, an issue in JIRA can be anything in the real world to represent a unit of work or a task to be completed. In this section, we will look at how JIRA presents an issue in the user interface for JIRA Core and JIRA Software. We will cover JIRA Service Desk in [Chapter 11, JIRA Service Desk](#), as it has a different interface.

Let's first take a look at an issue in JIRA Core. The following screenshot shows a typical example of an issue and breaks it down into more digestible sections, followed by an explanation of each of the highlighted sections in a table. This view is often called the **issue summary** or the **view issue** page:

The screenshot shows a JIRA issue summary page for issue #CON_7829. The page is titled "Send contract document for #CON_7829 issue summary". It includes the following sections:

- Details:** Shows issue operations (Type: Task, Priority: Medium, Affects Version/s: None, Component/s: Review, Labels: None) and workflow transitions (Status: TO DO, Resolution: Unresolved, Fix Version/s: None).
- Issue details:** Description: "Please send the attached contract for review and approval." Attachments: A PDF file named "contract.pdf" (14 minutes ago, 106 kB).
- People:** Assignee: Tom Johnson (with options to assign to me, remove vote, or stop watching), Reporter: John Kennedy.
- Dates:** Created: 10 Jul 16 9:16 PM, Updated: 12 minutes ago.
- Attachments:** A section showing the uploaded PDF file.
- Sub-Tasks:** A list of three tasks: "Prepare contract document" (DONE, John Kennedy), "Review contract with legal team" (DONE, Tom Johnson), and "Contact and send contract document for signature" (TO DO, Unassigned).
- Activity:** A comment from Patrick Li: "Patrick Li added a comment - 12 minutes ago. Please send this to legal for review." A "Comment" button is also present.
- Comments and other data:** A summary of the activity and attachments.

These sections are described in the following table:

Section	Description

project/issue key	This shows the project the issue belongs to. The issue key is the unique identifier of the current issue. This section acts as a breadcrumb for easy navigation.
issue summary	This is a brief summary of the issue.
issue export options	These are the various view options for the issue. The options include XML, Word, and Printable.
issue operations	These are the operations that users can perform on the issue, such as edit, assign, and comment. These are covered in the later sections of this chapter.
workflow options	These are the workflow transitions available. Workflows will be covered in Chapter 7, Workflows and Business Processes .
issue details /fields	This section lists the issue fields such as issue type and priority. Custom fields are also displayed in this section. Fields will be covered in Chapter 5, Field Management .
user fields	This section is specific for user-type fields such as assignee and reporter. Fields will be covered in Chapter 5, Field Management .
date fields	This section is specific for date-type fields such as create and due date. Fields will be covered in Chapter 5, Field Management .
attachments	These list all the attachments in an issue.
sub-tasks	Issues can be broken down into smaller sub-tasks. If an issue has sub-tasks, they will be listed in this section.
comments	These list all the comments that are visible to the current user.
work log	These list all the time tracking information your users have logged again the issue. See <i>time tracking</i> section for more details.
history	Keeps track all changes that have occurred for this issue, including values

before and after the change.

activity	Similar to history above, but is formatted in a more user friendly way. Can also generate an RSS feed for the content.
-----------------	--

JIRA Software, when running Scrum or Kanban, uses the agile board user interface, which represents issues as cards on a board, as described in [Chapter 3, Using JIRA for Agile Projects](#), which has a more concise summary of issues. However, when you click on the card, JIRA will expand and display the detailed information of the issue, as shown in the preceding table.

Working with issues

As we saw, issues are the center of JIRA. In the following sections, we will look at what you, as a user, can do with issues. Note that each of the actions will require you to have specific permissions, which we will cover in [Chapter 9, Securing JIRA](#).

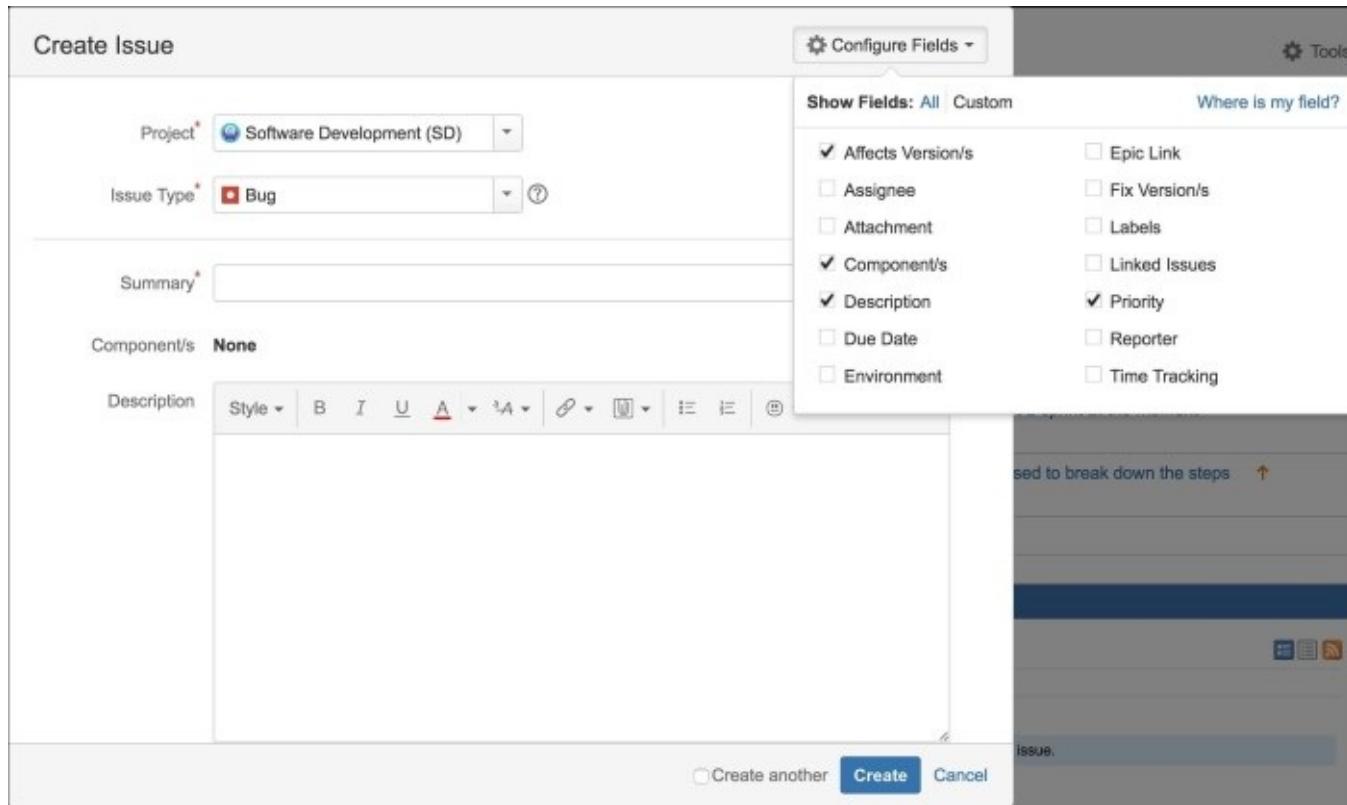

Creating an issue

When creating a new issue, you will need to fill in a number of fields. Some fields are mandatory, such as the issue's summary and type, while others are optional, such as the issue's description. We will discuss fields in more details in the next chapter.

There are several ways in which you can create a new issue in JIRA. You can choose any of the following options:

- Click on the **Create** button at the top of the screen
- Press **C** on your keyboard

This will bring up the **Create Issue** dialog box, as shown in the following screenshot:

As you can see, there are quite a few fields, and the required fields will have a red asterisk (*) mark next to their names.

The administrator configures what fields will be part of the create dialog, but as a user, you can customize and make your own create screen by hiding the optional fields, by performing the following steps:

1. Click on the **Configure Fields** option in the top-right corner.
2. Select the **Custom** option.
3. Uncheck all the fields you want to hide, and check the fields that you want to display, as

shown in the preceding screenshot.

Note

You are only hiding or showing these fields for yourself. Only the JIRA administrator can actually hide and show fields globally for all users.

There is a **Create another** option beside the **Create** button. By ticking this option and then clicking on the **Create** button, the **Create Issue** dialog box will stay on the screen and remember the values you have previously entered, such as priority, components, and due dates. This way, you can avoid having to fill in the whole dialog box again and will only have to update some of the fields that actually are different, such as **Summary**. With this feature, you can rapidly create many issues in a much shorter time frame.

Editing an issue

There are two ways in which you can edit an issue in JIRA. The first and more traditional way is by clicking on the **Edit** button or by pressing **E** on your keyboard. This will bring up the **Edit Issue** dialog box with all the editable fields for the current issue. This allows you to make changes to multiple fields at once.

The second option is called in-line editing. With this feature, you will be able to view the issue and edit the field you want on the spot, without having to wait for the edit dialog to load. Scroll down to find the field. To edit a field in-line, all you have to do is hover your mouse over the value for the field you want to update, wait for the **Edit** icon to show up, click on the icon, and start editing:

The screenshot shows the JIRA issue details screen for a story. At the top, there is a navigation bar with buttons for Edit, Comment, Assign, More, To Do, In Progress, Done, and Admin. Below the navigation bar, there is a section titled "Details" containing various issue fields. The "Type" field is set to "Story". The "Priority" field is set to "Medium". The "Labels" field is set to "None". The "Sprint" field is set to "SCRUM Sprint 1". The "Source" field is set to "Customer". To the right of the "Type" field, there is a status section with "Status: TO DO (View Workflow)" and "Resolution: Unresolved". A red text overlay "hover over, click, and edit" is placed over the "Status" section. Below the "Details" section, there is a "Description" section with a text area containing the message "Story and task issue's status cannot be updated currently from the UI." and an edit icon.

The fields you can edit are controlled by the screen used for the edit issue operation. Screens will be discussed in [Chapter 6, Screen Management](#).

Deleting an issue

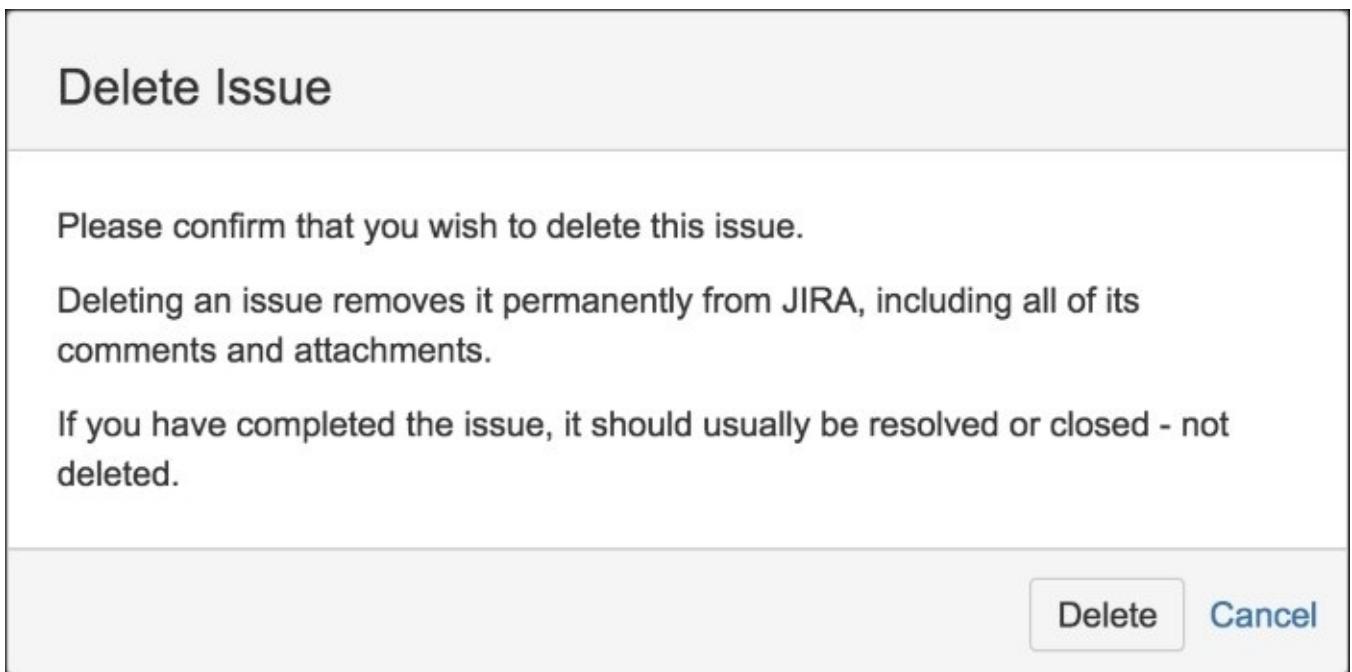

You can delete issues from JIRA. You might need to delete issues that have been created by mistake or if the issue is redundant, although normally, it is better to close and mark the issue as a duplicate. We will discuss closing an issue in [Chapter 7, Workflows and Business Processes](#).

Note

Issue deletion is permanent in JIRA. Unlike some other applications that may put deleted records in a trash bin, which you can retrieve later, JIRA completely deletes the issue from the system. The only way to retrieve the deleted issue is by restoring JIRA with a previous backup.

Perform the following steps to delete an issue:

1. Browse to the issue you wish to delete.
2. Click on the **Delete** option from the **More** menu. This will bring up the **Delete Issue** dialog box:

3. Click on the **Delete** button to remove the issue permanently from JIRA.

Deleting an issue permanently removes it from JIRA, along with all of its data, including attachments and comments.

Moving an issue between projects

Once an issue has been created, the issue is associated with a project. You can, however, move the issue around from one project to another. This may sound like a very simple process, but there are many steps involved and things to be considered.

First, you need to decide on a new issue type for the issue if the current issue type does not exist in the new project. Second, you will need to map a status of the issue. Third, you will need to decide on the values for the fields that exist in the new project but which do not exist in the current project if those fields are set to mandatory in the new project. Sounds like a lot? Luckily, JIRA comes with a wizard that is designed to help you address all those items.

Perform the following steps to start moving an issue:

1. Browse to the issue you wish to move.
2. Click on the **Move** option in the **More** menu. This will bring up the **Move Issue** wizard.

There are essentially four steps in the **Move Issue** wizard.

The first step is to select which project you wish to move the issue too. You will also need to select the new issue type. If the same issue type exists in the new project, you can usually continue to use the same issue type:

Move Issue

Move Issue: HR-1 - Test

Step 1 of 4: Choose the project and issue type to move to ...

Select Project

Current Project: Human Resource → New Project: Publication Tasks (PUB)

Select Issue Type

Current Issue Type: Task → New Issue Type: Task

Next >> Cancel

The second step allows you to map the current issue to the new project's workflow. If the issue's status exists in the target project, the wizard will skip this step:

Move Issue

<ul style="list-style-type: none">● Select Project and IssueType Project: Publication Tasks Issue Type: Task● Select New Status● Update Fields● Confirmation	<p>Move Issue: Select Status</p> <p>Step 2 of 4: Select the status of the issue ...</p> <p>Note: Each status displayed below is invalid - please select a new status.</p> <p>Current Issue (Workflow: classic default workflow → PUB: Task Management Workflow)</p> <p>Current Status: OPEN → New Status: To Do</p> <p>Next >> Cancel</p>
--	---

The third step shows all the fields that exist in the new project but not the current project and which require a value. Again, if there are no missing fields, this step will be skipped:

<ul style="list-style-type: none">● Select Project and IssueType Project: Publication Tasks Issue Type: Task● Select New StatusStatus: To Do● Update Fields● Confirmation	<p>Move Issue: Update Fields</p> <p>Step 3 of 4: Update the fields of the issue to relate to the new project.</p> <p>* Publication Date: <input type="text" value="12/Aug/16"/> Calendar</p> <p>Next >> Cancel</p>
---	--

The fourth and last step shows you the summary of the changes that will be applied by moving the issue from project A to project B. This is your last chance to make sure that all the information is correct. If there are any mistakes, you can go back to step one and start over again. If you are happy with the changes, confirm the move by clicking on **Move**:

Move Issue

- Select Project and Issue Type
Project: **Publication Tasks**
Issue Type: **Task**
- Select New Status Status: **To Do**
- Update Fields
- Confirmation

Move Issue: Confirm

Step 4 of 4: Confirm the move with all of the details you have just configured.

	Original Value (before move)	New Value (after move)
Project	Human Resource	Publication Tasks
Type	Task	Task
Status (Workflow)	OPEN (classic default workflow)	TO DO (PUB: Task Management Workflow)
Publication Date		12/Aug/16

Move **Cancel**

Once the issue is moved, it will be given a new issue key based on the new project. However, JIRA is still able to redirect you if you access the issue with its old issue key.

Casting a vote on an issue

The most straightforward way to express your interest in a JIRA issue is to vote for it. For organizations or teams that manage their priorities based on popularity, voting is a great mechanism to collect this information.

An example of this is how Atlassian uses JIRA (for example, <https://jira.atlassian.com/browse/JRA-9>) as a way to let its customers choose and vote for the features they want to be implemented or bugs to be fixed by voting on issues based on their needs. This allows the product management and marketing team to have an insight into the market needs and how to best evolve their offerings.

One thing to keep in mind is when voting is that you can only vote once per issue. You can vote many times for many different issues, but for any given issue, you have only one vote. This helps prevent a single user from continuously voting on the same issue, which may blow the final statistics out of proportion. You can, however, unvote a vote you have already cast on an issue, and vote for it again later; if you choose to do this, it will still only count as one vote.

To vote for an issue, simply click on the **Vote for this issue** link next to **Votes**. When you have voted for an issue, the icon will appear colored. When you have not yet voted for an issue, the icon will appear gray. Note that you cannot vote for issues that you have created.

Receiving notifications on an issue

JIRA is able to send automated e-mail notifications about updates on issues to users. Normally, notification e-mails will only be sent out to the issue's reporter, assignee, and people who have registered interest in the issue. This behavior can be changed through **Notification Schemes**, which we will discuss in [Chapter 8, E-mails and Notifications](#).

You can register your interest in the issue by choosing to watch the issue. By watching an issue, you will receive e-mail notifications on activity updates. Users watching the issue can also choose to stop watching, thus stop receiving e-mail updates from JIRA. You can also add other users as watchers by adding them to the watcher's list.

To watch an issue, simply click on the **Start watching this issue** link. If you are already watching the issue, it will change to **Stop watching this issue**. If you click on the link again, you will stop watching the issue, as shown in the following screenshot:

The screenshot shows the 'People' section of a JIRA issue page. It displays the following fields:

- Assignee:** Tom Johnson (with a blue profile icon)
- Reporter:** Patrick Li (with a brown profile icon)
- Votes:** 0
- Watchers:** 2 Stop watching this issue (with a blue button)

A modal window titled "Add Watchers" is open, containing a search bar with the placeholder "Start Typing for Users". Below the search bar are two user entries:

- Kim Lee (with a yellow profile icon)
- Patrick Li (with a brown profile icon)

Note

JIRA will automatically add you as a watcher for issues created by you.

JIRA also shows how many people are actively watching the issue by displaying the total watchers next to the watch icon. You can click on the number next to **Watchers** to see the full list of watchers.

Assigning issues to users

Once an issue has been created, the user normally assigned to the issue will start working on it. Afterward, the user can assign the issue further, for example, to QA staff for further verification.

There are many instances where an issue needs to be reassigned to a different user, for example, when the current assignee is unavailable or if issues are created with no specific assignees. Another example is where issues are assigned to different people at different stages of the workflow. For this reason, JIRA allows users to reassign issues once they have been created.

Perform the following steps to assign an issue:

1. Browse to the issue you wish to assign.
2. Click on the **Assign** button in the **Issue** menu bar or press **A** on your keyboard (you can also use the **in-line edit** feature here). This will bring up the **Assign** dialog.
3. Select the new assignee for the issue and optionally add a comment to provide some information to the new assignee.
4. Click on the **Assign** button:

Assign

Assignee

[Assign to me](#)

Comment

Please take a look at this issue for me, thanks.

Viewable by All Users

Shortcut tip: Pressing also opens this dialog box

Once this issue has been reassigned, its assignee's value will be updated to the new user. The new assignee will also receive a notification e-mail, alerting them of the assignment. You can also un-assign an issue this way by simply selecting the **Unassigned** option. Unassigned issues do not have an assignee and will not show up on anyone's list of active issues.

Tip

You can press **I** on your keyboard to quickly assign the issue to yourself.

Sharing issues with other users

If you want to e-mail an issue to other users in JIRA, instead of having to manually copy and paste the issue's URL in an e-mail, you can use the built-in share feature in JIRA. All you have to do is go to the issue you want to share and click on the share icon, as shown in the following screenshot, or press **S** on your keyboard. Then select the users you want to share the issue with and click on the **Share** button:

Export ▾

Link to Issue

<http://jira.example.com/browse/HR-1>

User name or email

Tom Johnson

Kim Lee

Note

Hey, any thoughts on this?

Share

Cancel

Note

If the user you are sharing the issue with does not have access to the issue, they will not be able to see the issue's details.

Issue linking

JIRA allows you to create custom hyperlinks for issues. This allows you to provide more information about the issue. There are two types of links you can create: linking to other issues in JIRA or linking to any arbitrary resources on the Web, such as a web page.

Linking issues with other issues

Issues are often related to other issues in some way. For example, issue A might be blocking issue B, or issue C might be a duplicate of issue D. You can add descriptions to the issue to capture this information, or delete one of the issues in the duplication case, but with this approach, it is hard to keep a track of all these relationships. Luckily, JIRA provides an elegant solution for this, with the standard issue link feature.

The **standard issue link** lets you link an issue with one or more other issues in the same JIRA instance. So, you can link two issues from different projects together (if you have access to both the projects). Linking issues in this way is very simple; all you need to know is the target issues to link to:

1. Browse to the **view issue** page for the issue you wish to create a link for.
2. Select **Link** from the **More** menu. This will bring up the **link issue** dialog box.
3. Select the **JIRA Issue** option from the left panel.
4. Select the type of issue linking from the **This issue** drop-down menu.
5. Select the issues to link to. You can use the search facility to help you locate the issues you want.
6. Click on the **Link** button:

The screenshot shows the 'Link' dialog box in JIRA. The left sidebar has 'JIRA Issue' selected. The main area is titled 'Select a JIRA issue to link this issue to'. It shows 'This issue' is set to 'relates to'. Below it is a list box containing 'PUB-4' and 'PUB-2', with a placeholder 'or search for an issue' and a note 'Begin typing to find recently viewed issues'. At the bottom, there's a 'Comment' section with a rich text editor toolbar and a large text area. The bottom right of the dialog has 'Link' and 'Cancel' buttons.

After you have linked your issues, they will be displayed in the **Issue Links** section on the **View Issue** page. JIRA will display the target issue's key, description, priority, and status.

Linking issues with remote contents

The standard JIRA issue link allows you to link multiple issues to the same JIRA instance. JIRA also lets you link issues to resources such as a web page on the Internet.

Using remote issue links is quite similar to the standard issue link; the difference is that instead of selecting another issue, the URL address of the target resource is specified:

1. Open up the **Link Issue** dialog box.
 2. Select the **Web Link** option from the left panel.
 3. Specify the URL address for the target resource. JIRA will automatically try to find and load the appropriate icon for the resource.
 4. Provide the name for the link in **Link Text** field. The name you provide here will be what is shown for the link when viewing the issue.
 5. Click on the **Link** button:

Link

<p>JIRA Issue</p> <p>Web Link</p>	<p>Enter a URL to link this issue to</p> <p>URL* <input type="text" value="https://en.wikipedia.org/wiki/Jira_(software)"/></p> <p>Enter the URL of the page to link</p> <p>Link Text* <input type="text" value="Wikipedia on JIRA"/></p> <p>Comment</p> <div style="border: 1px solid #ccc; padding: 5px; height: 150px;"> <p>Style ▾ B I U A ▾ ▾ A ▾ ⌂ ▾ E E</p> <p>✎ ▾ + ▾</p> </div> <p> </p> <p> Viewable by All Users</p>
---	---

Issue cloning

When you need to create a new issue and you already have a baseline issue, JIRA allows you to quickly create it with the data based on your existing issues by cloning the original one. Cloning an issue allows you to quickly create a new one with most of its fields populated. For example, you might have two software products with the same bug. After creating a bug report in one project, you can simply clone it for the other project.

A cloned issue will have all the fields copied from the original issue; however, it is a separate entity nonetheless. Further actions performed on either of the two issues will not affect the other.

When an issue is being cloned, a **Clone** link is automatically created between the two issues, establishing a relationship.

Cloning an issue in JIRA is simple and straightforward. All you have to do is specify a new summary (or accept the default summary with the text CLONE at the front) for the cloned issue:

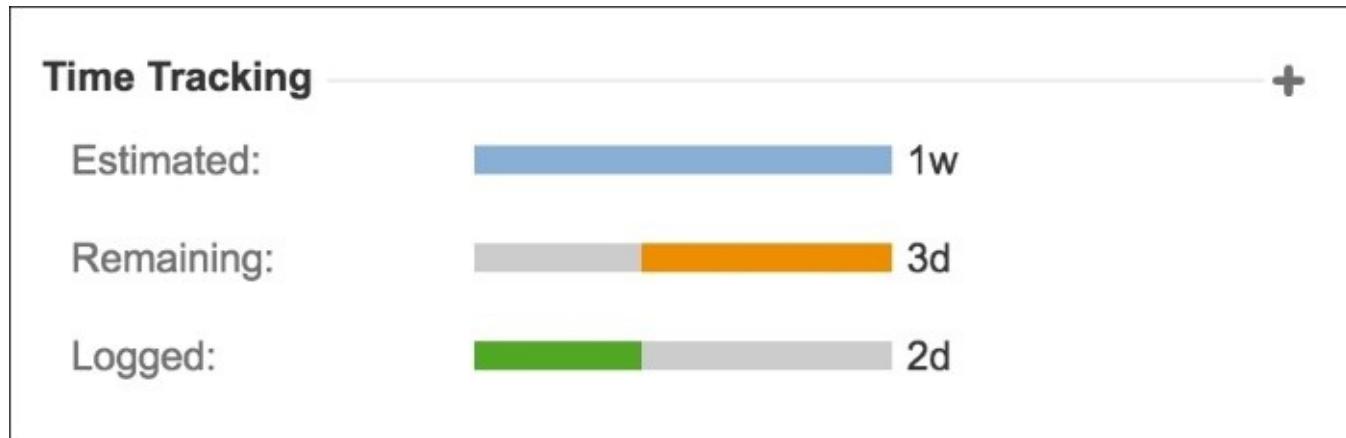

1. Browse to the issue you wish to clone.
2. Select **Clone** from the **More** menu.
3. Type in a new summary for the new cloned issue.
4. Check the **Clone Sub Tasks** check box if you also want to copy over all the subtasks.
5. Click on the **Create** button.

Once the issue is successfully cloned, you will be taken to the issue summary page for the newly cloned issue.

Time tracking

Since issues often represent a single unit of work that can be worked on, it is logical for users to log the time they have spent working on it. You can specify an estimated effort required to complete an issue, and JIRA will be able to help you track the progress.

JIRA displays the time tracking information of an issue in the **Time Tracking** panel on the right-hand side, as shown in the following screenshot:

- **Estimated:** This represents the original estimated effort required to complete the issue, for example, the estimated time required to fix a bug by a developer.
- **Remaining:** This represents the remaining time for the issue to be completed. It is calculated automatically by JIRA based on the original estimate and total time logged by users. However, the user logging work on the issue, as described in the following section, can also override this value.
- **Logged:** This represents the total time spent on the issue so far.

Specifying original estimates

Original estimate represents the anticipated time required to complete the work represented by the issue. It is shown as the blue bar under the **Time Tracking** section.

In order for you to specify an original estimate value, you need to make sure that the **Time Tracking** field is added to the issue's create and/or edit screen. We will discuss fields and screens in [Chapter 5, Field Management](#), and [Chapter 6, Screen Management](#), respectively.

To specify an original estimate value, provide a value for the **Original Estimate** field when you are creating or editing an issue.

Logging work

Logging work in JIRA allows you to specify the amount of time (work) you have spent working on an issue. You can log work against any of the issues, provided you have the permission to do so. We will cover permissions in [Chapter 10, Searching, Reporting, and Analysis](#).

Perform the following steps to log work against an issue:

1. Browse to the issue you wish to log work against.
2. Select **Log Work** from the **More** menu.
3. Enter the amount of time you wish to log. Use **w**, **d**, **h**, and **m** to specify week, day, hour, and minute, respectively.
4. Select the date you wish to log your work against.
5. Optionally, select how the remaining estimate should be adjusted.
6. Add a description to the work you have done.
7. Optionally, select who can view the work log entry.
8. Click on the **Log** button.

When you log work on an issue, you have the option to choose how the **Remaining Estimate** value will be affected. By default, this value will be automatically calculated by subtracting the amount logged from the original estimate. You can, however, choose other options available, such as setting the remaining estimate to a specific value or reducing it by an amount that is different from the amount of work being logged.

Tip

You can also click on the + sign in the **Time Tracking** section to log time.

Issues and comments

JIRA lets users create comments on issues. As we have already seen, you will be able to create comments when assigning an issue to a different user. This is a very useful feature that allows multiple users to collaborate to work on the same issue and share information. For example, the support staff (issue assignee) may request more clarification from the business user (issue reporter) by adding a comment to the issue. When combined with JIRA's built-in notification system, automatic e-mail notifications will be sent to the issue's reporter, assignee, and any of the other users watching the issue. Notifications will be covered in [Chapter 8, E-mails and Notifications](#).

Adding comments

By default, all logged-in users will be able to add comments to issues they can access. Perform the following steps to add a comment to an issue:

1. Browse to the issue you wish to add a comment to.
2. Click on the **Comment** button or press **M** on your keyboard.
3. Type a comment in to the text box. You can preview and set restrictions on who can view your comment.
4. Click on the **Add** button to add the comment:

The screenshot shows a software interface for managing comments. At the top, there's a navigation bar with tabs: 'All', 'Comments' (which is currently selected), 'Work Log', 'History', and 'Activity'. Below the navigation bar, a message says 'There are no comments yet on this issue.' Under the 'Comments' tab, there's a text area with a rich text editor toolbar above it. The text area contains the comment 'Please attach the error logs to this ticket.' At the bottom of the comment area, there's a dropdown menu with options like 'Viewable by All Users' and 'Viewable by Selected Users'. A red box highlights the 'Viewable by All Users' option, indicating it is being changed. At the very bottom of the interface, there are 'Add' and 'Cancel' buttons.

Once a comment has been added, the comment will be visible in the **Comments** tab in the **Activity** section at the bottom. When you are creating comments, you can select who can view your comment using the comment access control. This is very useful if you have external users viewing the issue and you only want to share your comments with internal users.

After you have added your comment to an issue, you can edit its contents and security settings or delete it altogether. To edit or delete a comment, simply hover over the comment, and the comment management option will appear on the right-hand side:

Activity

All Comments Work Log History Activity

Patrick Li added a comment - 1 minute ago

Please attach a screenshot of the error message to this issue.

[permalink](#), [edit](#), [delete](#) this comment

Permalinking a comment

From time to time, you will want to refer other people to a comment you made previously. While you can tell them the issue and let them scroll down to the bottom until they find your comment among hundreds of others, JIRA allows you to create a quick permalink to your comment that will take you directly to the comment of interest.

Perform the following steps to create a permalink for a comment:

1. Browse to the comment you wish to a permalink.
2. Hover over the comment to bring up the comment management options.
3. Click on the permalink icon. This will highlight the comment in pale blue.

You will now notice that your browser's URL bar will have something similar to <http://sample.jira.com/browse/DEMO-1?focusedCommentId=10100&page=com.atlassian.jira.plugin.system.issuetabpanels:comment-tabpanel#comment-10100> as a sample link (note the focusedCommentId section after the issue key). Copy and paste that URL and give it to your colleagues; once they click on this link, they will be taken directly to the highlighted comment.

Attachments

As we have seen so far, JIRA uses fields such as **Summary** and **Description** to capture data. This works for most cases, but when you have complex data such as application log files or screenshots, this becomes insufficient. This is where attachments come in. JIRA allows you to attach files from your local computer or a screenshot you have taken.

Attaching files

The easiest way to attach a file to a JIRA issue is via the drag and drop action:

1. Browse to the issue you wish to attach a file to.
2. Drag and drop the files you want to attach in to the browser. You will see an outline indicating where you can drop the file to attach it to the issue, as shown in the following screenshot:

The screenshot shows a JIRA issue page for 'Scrum / SCRUM-4'. At the top, there's a message: 'As a developer, I can update stories by drag and drop (click the triangle at far left of this story to show sub-tasks)'. Below this are standard JIRA navigation buttons: Edit, Comment, Assign, More, To Do, In Progress, Done, Admin. To the right are Export and Print buttons. The main content area has two main sections: 'Details' and 'Attachments'. The 'Details' section includes fields for Type (Story), Priority (Medium), Labels (None), Sprint (SCRUM Sprint 1), and Source (Customer). The 'Attachments' section shows a file named 'apache_logs_sample.txt' with a 'Drop files to attach, or browse.' button below it. To the right of these sections are 'People' and 'Dates' sections. The 'People' section lists Assignee (Kim Lee) and Reporter (Tom Johnson). The 'Dates' section shows Created (empty). A yellow box highlights the 'Drop files to attach them to the issue' area above the attachments section.

Drag and drop is the easiest way to attach files. But if for some reason drag and drop does not work, you can also manually select the file and attach it:

1. Browse to the issue you wish to attach a file to.
2. Select the **Attach files** option from the **More** menu.
3. Select and attach the files you want to attach from the file browser.

Depending on the file's type, certain files such as images and PDF can be viewed directly from the JIRA's UI without having to download it.

Attaching screenshots

Apart from letting you attach any file to an issue, JIRA also allows you to directly attach a screenshot from your system clipboard to issues. This saves you from having to take a screenshot, save it as a physical file on the disk, and finally attach it to JIRA.

Perform the following steps to attach a screenshot:

1. Take a screenshot with your operating system. For example, if you are on Windows, press the ***Print Screen*** key.
2. Browse to the issue you wish to attach a screenshot:

Attach Screenshot

Take a screenshot: **^ Ctrl + ⌘ Cmd + ⌄ Shift + 3**

Paste the image: **⌘ Cmd + V**

The screenshot shows a 'Create Issue' dialog box. At the top, there is a 'Configure Fields' button. Below it, the 'Project' field is set to 'Software Development (SD)'. The 'Issue Type' field is set to 'Bug'. The 'Summary' field is empty. The 'Reporter' field shows a user icon and the name 'Patrick Li'. Below these, the 'Component/s' field is set to 'None'. The 'Description' field contains a rich text editor toolbar. At the bottom right of the dialog are buttons for 'Create another', 'Create', and 'Cancel'.

File name* **screenshot-1**

A file name to be used as attached image name

Upload **Cancel**

3. Press the *Ctrl + V* keys on your keyboard, and the screenshot will be pasted into the preceding panel.
4. Enter a file name for the screenshot or accept the default name.
5. Click on the **Upload** button.

Issue types and subtasks

As seen earlier, issues in JIRA can represent many things ranging from software development tasks to project management milestones. Issue type is what differentiates one kind of issue from another.

Each issue has a type (therefore, the name issue type), which is represented by the issue type field. This lets you know what type of issue it is and also helps you determine many other aspects of it, such as which fields will be displayed for this issue.

The default issue types are great for simple software development projects, but they do not necessarily meet the needs of others. Since it is impossible to create a system that can address everyone's needs, JIRA lets you create your own issue types and assigns them to projects. For example, for a help desk project, you might want to create a custom issue type called ticket. You can create this custom issue type and assign it to the **Help Desk** project and users will be able to log tickets, instead of bugs, in the system.

Issue types are managed through the **Manage Issue Types** page. Perform the following steps to access this page:

1. Log in to JIRA as a JIRA administrator.
2. Browse to the JIRA administration console.
3. Select the **Issues** tab and then the **Issue types** option. This will take you to the **Issue Types Administration** page.

The following screenshot shows a list of default issue types that come with JIRA Software. If you only have JIRA Core, the list may look different:

Issue types			
Name	Type	Related Schemes	Operations
Bug A problem which impairs or prevents the functions of the product.	Standard	<ul style="list-style-type: none">SD: Software Development Issue Type SchemeSCRUM: Scrum Issue Type SchemeKANBAN: Kanban Issue Type Scheme	Edit · Delete · Translate
Epic gh.issue.epic.desc	Standard	<ul style="list-style-type: none">Default Issue Type SchemeSD: Software Development Issue Type SchemeSCRUM: Scrum Issue Type SchemeKANBAN: Kanban Issue Type Scheme	Edit · Delete · Translate
Improvement An improvement or enhancement to an existing feature or task.	Standard	<ul style="list-style-type: none">SD: Software Development Issue Type Scheme	Edit · Delete · Translate
New Feature A new feature of the product, which has yet to be developed.	Standard	<ul style="list-style-type: none">SD: Software Development Issue Type Scheme	Edit · Delete · Translate
Story gh.issue.story.desc	Standard	<ul style="list-style-type: none">Default Issue Type SchemeSCRUM: Scrum Issue Type SchemeKANBAN: Kanban Issue Type Scheme	Edit · Delete · Translate

Creating issue types

You can create any number of issue types. Perform the following steps to create a new issue type:

1. Browse to the **Issue Types Administration** page.
2. Click on the **Add Issue Type** button.
3. Enter the name and description for the new issue type.
4. Select whether the new issue type will be a standard issue type or a subtask issue type.
5. Click on **Add** to create the new issue type.

Once the new issue type is created, it will be assigned a default icon. If you want to change the icon, you will need to click on the **Edit** link for the issue type and then select a new image as its icon.

Deleting issue types

When deleting an issue type, you have to keep in mind that the issue type might already be in use, meaning that there are issues created with that issue type. So, when you delete an issue type, you will need to select a new one for those issues. The good news is that JIRA takes care of this for you. As shown in the following screenshot, we delete the **Bug** issue type and JIRA informs us of the already existing 6 issues of type **Bug**. You will need to assign them to a new issue type, such as **Improvement**:

Delete Issue Type: Bug [click to view the 6 issues using this issue type](#)

Note: This issue type cannot be deleted - there are currently **6** matching issues with no suitable alternative issue types (only issues you have permission to see will be displayed, which may be different from the total count shown on this page).

In order for an issue type to be deleted, it needs to be associated with one workflow, field configuration and field screen scheme across all projects. If this is not the case, JIRA can not provide a list of valid replacement issue types.

[Cancel](#)

Subtasks

JIRA allows only one person (assignee) to work on one issue at a time. This design ensures that an issue is a single unit of work that can be tracked against one person. However, in the real world, we often find ourselves in situations where we need to have multiple people working on the same issue. This may be caused by a poor breakdown of tasks or simply because of the nature of the task at hand. Whatever the reason, JIRA provides a mechanism to address this problem through subtasks.

Subtasks are similar to issues in many ways, and as a matter of fact, they are a special kind of issue. They must have a parent issue, and their issue types are flagged as subtask issue types. You can say that all subtasks are issues, but not all issues are subtasks.

For every issue, you can have one or more subtasks that can be assigned and tracked separately from another. Subtasks cannot have other subtasks. JIRA allows only one level of subtasks.

Creating subtasks

Since subtasks belong to an issue, you need to browse to the issue first before you can create a new subtask:

1. Browse to the issue you wish to create subtasks for.
2. Select **Create Sub-Task** from the **More** menu.

You will see a familiar **Create Issue** dialog box. However, one thing you will notice is that, unlike when you are creating an issue, you do not select which project to create the subtask in. This is because JIRA can determine the project value based on the parent issue. You will also notice that you can only select issue types that are subtasks.

Other than these differences, creating a subtask is no different than creating a normal issue. You can customize the fields shown in the dialog box and choose to rapidly create multiple subtasks by selecting the **Create another** option.

Once the subtask has been created, it will be added to the **Sub-Tasks** section of the parent issue. You will see all the subtasks that belong to the issue and their status. If a subtask has been completed, it will have a green tick next to it:

Sub-Tasks			
1.	Prepare contract document	<input checked="" type="checkbox"/>	DONE John Kennedy
2.	Review contract with legal team	<input checked="" type="checkbox"/>	DONE Tom Johnson
3.	Contact and send contract document for signature	<input type="checkbox"/>	TO DO Unassigned

Issue type schemes

Issue type schemes are templates or collections of issue types that can be applied to projects. As shown in the following screenshot, JIRA comes with **Default Issue Type Scheme**, which is applied to all projects that do not have specific issue type schemes applied. When you create a new project, a new issue type scheme is created for you based on the project template you have selected. The new scheme will also have issue types prepopulated based on the template. As we can see in the following screenshot, we have two issue type schemes, **TP: Project Management Issue Type Scheme** for **Test Project** and **SD: Software Development Issue Type Scheme** for the **Software Development** project:

Issue type schemes			
Name	Options	Projects	Operations
Default Issue Type Scheme Default issue type scheme is the list of global issue types. All newly created issue types will automatically be added to this scheme.	<input checked="" type="checkbox"/> Epic <input checked="" type="checkbox"/> Story	Global (all unconfigured projects)	Edit · Associate · Copy
TP: Project Management Issue Type Scheme	<input checked="" type="checkbox"/> Task (Default) <input type="checkbox"/> Sub-task	• Test Project	Edit · Associate · Copy · Delete
SD: Software Development Issue Type Scheme	<input checked="" type="checkbox"/> Improvement <input checked="" type="checkbox"/> Task <input type="checkbox"/> Sub-task <input checked="" type="checkbox"/> New Feature <input type="checkbox"/> Bug (Default) <input checked="" type="checkbox"/> Epic	• Software Development	Edit · Associate · Copy · Delete

When you create your own issue types, in order to make them available, you need to add them to the issue type scheme used by your project.

Adding issue types to an issue type scheme

Perform the following steps to create a new issue type scheme:

1. Browse to the administration console.
2. Select the **Issues** tab and then the **Issue type schemes** option. This will bring you to the **Issue Type Schemes** page.
3. Click on the **Edit** link for the issue type scheme you want to add issue types too.
4. Drag the issue types you want to be part of the scheme from the **Available Issue Types** list and drop them into the **Issue Types for Current Scheme** list.
5. Select a **Default Issue Type** value. Note that this is optional, and you can only select a default issue type after you have selected at least one issue type for the new scheme.
6. Click on the **Save** button:

Modify Issue Type Scheme — TP: Project Management Issue Type Scheme + Add Issue Type

SHARED BY 1 PROJECT

Scheme Name * TP: Project Management Issue Type S

Description

Default Issue Type Task

Change the order of the options by dragging and dropping the option into the desired order. Similarly, drag and drop the option from one list to the other to add or remove them.

Issue Types for Current Scheme	Available Issue Types
<p>Remove all</p> <p><input checked="" type="checkbox"/> Task</p> <p><input type="checkbox"/> Sub-task (sub-task)</p> <p><input type="checkbox"/> Bug</p>	<p>Add all</p> <p><input type="checkbox"/> Epic</p> <p><input type="checkbox"/> Story</p> <p><input type="checkbox"/> Improvement</p> <p><input type="checkbox"/> New Feature</p>

Save **Reset** **Cancel**

Issue priorities

Priorities help users to set the importance of issues. Users can first assign priority values to issues and later use them to sort the list of issues they have to work on, thus helping the team decide which issues to focus on first. JIRA comes with five levels of priorities out of the box, as shown in the following screenshot:

View Priorities					
The table below shows the priorities used in this version of JIRA, in order from highest to lowest.					
Name	Description	Icon	Color	Order	Operations
Highest	This problem will block progress.	↑	Red	↓	Edit · Delete · Default
High	Serious problem that could block progress.	↑	Magenta	↑ ↓	Edit · Delete · Default
Medium	Has the potential to affect progress.	↑	Orange	↑ ↓	Edit · Delete · Default
Low	Minor problem or easily worked around.	↓	Dark Gray	↑ ↓	Edit · Delete · Default
Lowest	Trivial problem with little or no impact on progress.	↓	Dark Gray	↑	Edit · Delete · Default

You can customize this list by creating your own priorities. To create new priorities, follow these steps:

1. Browse to the administration console.
2. Select the **Issues** tab and then the **Priorities** option.
3. Enter a name and description for the new priority.
4. Click on the **select image** link to choose an icon for the priority.
5. Specify a color for the priority. You can either type in the HTML color hex code directly or use the color picker to help you select the color you want. The color chosen here will be used when icon images cannot be displayed, such as when you export issues to a spreadsheet.
6. Click on the **Add** button.

Note

Priorities are global. This means that all projects will share the same set of priorities.

The HR project

In this exercise, we will continue our setup for the project we have created in the previous chapter. We will add the following configurations to our project:

- A set of new issue types that are specific to our HR project
- Add our new issue types to the issue type scheme to make them available

Adding new issue types

Since our project is for the human resources team, we need to create a few custom issue types to augment the default ones that come with JIRA. For this exercise, we will create two new issue types, **New Employee** and **Termination**.

The first step to set up an issue type association is to create the two issue types we need, incident and ticket:

1. Browse to the **Issue Types** page.
2. Click on the **Add Issue Type** button.
3. Type **New Employee** in the **Name** field.
4. Click on **Add** button to create the new issue type.

You should now see the new issue type in the table. Now, let's add the **Termination** issue type:

1. Click on the **Add Issue Type** button again.
2. Type **Termination** in the **Name** field.
3. Click on **Add** to create the new issue type.

You should see both the **New Employee** and **Termination** issue types. However, this will only make our new issue types available, but will not make them the only options when creating a new issue for our project. If you remember the previous sections, we need to add the new issue types to the issue type scheme used by our project.

Updating the issue type scheme

We want to limit the issue types to be only Incident and Ticket for our Global Help Desk project, but we do not want to affect the other projects that still need to have bug and other default issue types. So, we need to create a new issue type scheme specifically for support projects, which can be used by us and other teams:

1. Browse to the **Issue Type Schemes** page.
2. Click on the **edit** link for our issue type scheme. The default one created by JIRA should be called **HR: Task Management Issue Type Scheme**.
3. Drag the **New Employee** and **Termination** issue types from the **Available Issue Types** panel to the **Issue Types for Current Scheme** panel.
4. Click on the **Save** button.

Putting it together

With everything created and set up, you can go back and create a new issue to see how it all looks. If everything works out, you should see something similar to the following screenshot:

Create Issue Configure Fields ▾

Project *

Summary

In this chapter, we looked at what issues are in JIRA and explored the basic operations of creating, editing, and deleting issues. We also looked at the advanced operations offered by JIRA to enhance how you can manipulate and use issues, such as adding attachments, creating sub-tasks, and linking multiple issues.

In the next chapter, we will look at fields and how we can create our own custom fields to capture additional information from users.

Chapter 5. Field Management

Projects are collections of issues, and issues are collections of fields. As we have seen in the earlier chapters, fields are what capture data that can then be displayed to users. There are many different types of fields in JIRA, ranging from simple text fields that let you input alphanumeric texts, to more complicated fields with pickers to assist you with choosing dates and users.

An information system is only as useful as the data that goes into it. By understanding how to effectively use fields, you can turn JIRA into a powerful information system for data collection, processing, and reporting.

In this chapter, we will expand our **Help Desk** project with these customized fields and configurations, by exploring fields in detail and learning how they relate to other aspects of JIRA. By the end of this chapter, you will have learned the following:

- Understanding built-in and custom fields
- Collecting custom data through custom fields
- Adding behaviors to fields with field configurations
- Understanding field configuration schemes and how to apply them to projects

Built-in fields

JIRA comes with a number of built-in fields. You have already seen a few of them in the previous chapters. Fields such as summary, priority, and assignee are all built-in. They make up the backbone of an issue, and you cannot remove them from the system. For this reason, they are referred to as **system fields**.

The following table lists the most important built-in fields in JIRA:

System field	Description
Assignee	This specifies the user who is currently assigned to work on the issue.
Summary	This specifies a one-line summary of the issue.
Description	This provides a detailed description of the issue.
Reporter	This specifies the user who has reported this issue (although most of the time it is also the person who has created the issue, but not always).
Component/s	This specifies the project components the issue belongs to.
Effects Version/s	This specifies the versions the issue effects are found in.
Fix Version/s	This specifies the versions the issue will be fixed in.
Due Date	This specifies the date this issue is due.
Issue Type	This specifies the type of the issue (for example, Bug and New Feature).
Priority	This specifies how important the issue is compared to other issues.
Resolution	This specifies the current resolution value of the issue (for example, Unresolved or Fixed).

Time Tracking

This lets users estimate how long the issue will take to be complete.

Custom fields

While JIRA's built-in fields are quite comprehensive for basic general uses, most organizations soon find they have special requirements that cannot be addressed simply with the default fields available. To help you tailor JIRA to your organization's needs, JIRA lets you create and add your own fields to the system, called **custom fields**.

Custom field types

Every custom field belongs to a custom type, which dictates its behavior, appearance, and functionality. Therefore, when you add a custom field to JIRA, you really add another instance of a custom field type.

JIRA comes with over 20 custom field types that you can use straight out of the box. Many of the custom field types are identical to the built-in fields, such as date picker, which is like the due date field. They provide you with simplicity and flexibility that are not available with their built-in counterparts. The upcoming tables break down and list all the standard JIRA custom field types and their characteristics.

Standard fields

These fields are the most basic field types in JIRA. They are usually simple and straightforward to use, such as text field, which allows users to input any text:

Custom field type	Description
Date Picker	These are input fields that allow input with a date picker and enforce valid dates.
Date Time Picker	These are input fields that allow input with a date and time picker and enforce valid date timestamps.
Labels	These are input fields that allow tags to be added to an issue.
Number Field	These are input fields that store and validate numeric values.
Radio Buttons	These are radio buttons that ensure only one value can be selected.
Select List (cascading)	These are multiple select lists where the options for the second select list is dynamically updated based on the value of the first.
Select List (multiple choice)	These are multiple select lists with a configurable list of options.
Select List (single choice)	These are single select lists with a configurable list of options.
Text Field (multi-line)	These are multiple line text areas enabling entry of large text contents.
Text Field (single-line)	These are basic single line input fields that allow simple text inputs of less than 255 characters.
URL Field	These are input fields that validate a valid URL.

User Picker (single user)

These choose a user from the JIRA user base through either a pop-up user picker window or autocomplete.

Advanced fields

These fields provide specialized functions. For example, the `Version Picker` field lets you select a version from the current project. If you have any custom fields from third-party add-ons (see the following section), they will also be listed here:

Custom field type	Description
Group Picker (multiple group)	This chooses one or more user groups using a pop-up picker window.
Group Picker (single group)	This chooses a user group using a pop-up picker window.
Hidden Job Switch	This field type is used for Perforce integration with JIRA.
Job Checkbox	This field type is used for Perforce integration with JIRA.
Project Picker (single project)	This selects lists displaying the projects that are viewable to the user in the system.
Text Field (read only)	This is a read-only text field that does not allow users to set their data. It's only possible to programmatically set the data.
User Picker (multiple users)	This chooses one or more users from the user base through a pop-up picker window.
Version Picker (multiple versions)	This chooses one or more versions from the available versions in the current project.
Version Picker (single version)	This chooses a single version from the available versions in the project.

As you can see, JIRA provides you with a comprehensive list of custom field types. In addition, there are many custom field types developed by third-party vendors (available as **plugins** or **add-ons**) that you can add to your JIRA to enhance its functionality. These custom fields provide many specialized functionalities such as automatically calculating values and retrieving data from databases directly or connecting to an external system. Once you install

the plugin, the process of adding custom fields from other vendors is mostly the same as adding custom fields shipped with JIRA.

The following list shows some examples of plugins that provide additional useful custom fields. You can find them from the Atlassian Marketplace at <https://marketplace.atlassian.com>:

- **JIRA Enhancer Plugin:** This includes a number of custom fields that will automatically display dates when key events occur for an issue. For example, when the issue was last closed.
- **JIRA Toolkit Plugin:** This provides a number of useful custom fields such as showing the statistics on the users that participate in a given issue and the date when the issue was last commented on.
- **nFeed:** This provides a suite of custom fields that let you connect to databases, remote files, and web services to retrieve data and display them in JIRA.
- **21 CFR Part 11 E-Signature:** This lets users electronically sign issues in JIRA as they work on them, for example, approving an issue to be closed.
- **SuggestiMate for JIRA:** This provides a specialized custom field that shows similar and potentially duplicated issues when creating new issues or browsing through existing ones.

Searchers

For any information system, capturing data is only half of the equation. Users will need to be able to retrieve the data at a later stage, usually through searching, and JIRA is no different. While fields in JIRA are responsible for capturing and displaying data, it is their corresponding searchers that provide the search functionality.

All fields that come with JIRA have searchers associated by default, so you will be able to search issues by their summary or assignee, without any further configuration. Some custom fields from third-party add-ons may have more than one searcher available. You can change the default searcher applied by editing the custom field.

Note

In JIRA UI, a searcher is referred to as a **search template**.

Custom field context

Built-in fields, such as priority and resolution, are global across JIRA. What this means is that these fields will have the same set of selections for all projects. Custom fields, on the other hand, are a lot more flexible.

Custom field types, such as select list and radio buttons, can have different sets of options for different projects or different issue types within the same project. This is achieved through what is called a **custom field context**.

A custom field context is made up of a combination of applicable projects and applicable issue types. When you are working with an issue, JIRA will check the project and issue type of the current issue to determine if there is a specific context that matches the combination. If one is found, JIRA will load the custom field with any specific settings such as selection options. However, if no context is found, the custom field will not be loaded.

Note

In JIRA, if no context can be found that matches the project and issue type combination, a custom field does not exist for the issue.

We will look at how to set custom field contexts in a later section. What you need to remember now is when adding a custom field, you need to make sure that it has the correct context setting.

Managing custom fields

Custom fields are used globally across JIRA, so you will need to have the JIRA Administrator global permission to carry out management operations such as creation and configuration.

JIRA maintains all the custom fields in a centralized location for easy management. Perform the following steps to access the custom field management page:

1. Log in as a JIRA administrator user.
2. Browse to the JIRA administration console.
3. Select the **Issues** tab and then the **Custom fields** option:

Custom fields			
Name	Type	Available Context(s)	Screens
Department Department the issue belongs to.	Select List (single choice)	Issue type(s): Global (all issues)	• Default Screen 
Epic Name  Provide a short name to identify this epic.	Name of Epic	Issue type(s): 	Configure Edit Translate Screens Delete
Rank  Global rank field for JIRA Software use only.	Global Rank	Issue type(s): Global (all issues)	
Sprint  JIRA Software sprint field	JIRA Sprint Field	Issue type(s): Global (all issues)	
Story Points Measurement of complexity and/or size of a requirement.	Number Field	Issue type(s): 	

On the **Custom Fields** page, all the existing custom fields will be listed. From here, you can see the name of each custom field, their type, the context they belong to, and the screens they are displayed on.

Adding a custom field

Creating a new custom field is a multistep process, and JIRA provides a wizard to help you through it. There are two mandatory steps and an optional step when adding a new custom field. You need to first select the type of custom field, then its name, followed by options if you are adding a select list custom field type. The last, optional, step is to decide which screens to add the field onto. We will walk you through the process:

1. Browse to the **Custom Fields** page.
2. Click on the **Add Custom Field** button. This will bring you to step 1 of the process, where you can select the custom field type.
3. Search and select the custom field type you wish to add, and click on **Next**. This will bring you to step 2 of the process, where you can specify the custom field's name and options:

Select a Field Type

All

Standard

Advanced

Checkboxes

Choose multiple values using checkboxes.

Date Picker

A custom field that stores dates and uses a date picker to view them

Date Time Picker

A custom field that stores dates with a time component

Labels

Add arbitrary labels to issues.

Number Field

A custom field that stores and validates numeric (floating point) input.

Find More Custom Fields

Next Cancel

Tip

If you do not see the field type you are looking for, select the **All** option from the left-hand side and then search again.

4. Enter values for the **Name** and **Description** fields. If you are creating a selection-based custom field, such as a select list, you will need to add its select options, too (you can

update this list later):

Configure 'Select List (single choice)' Field

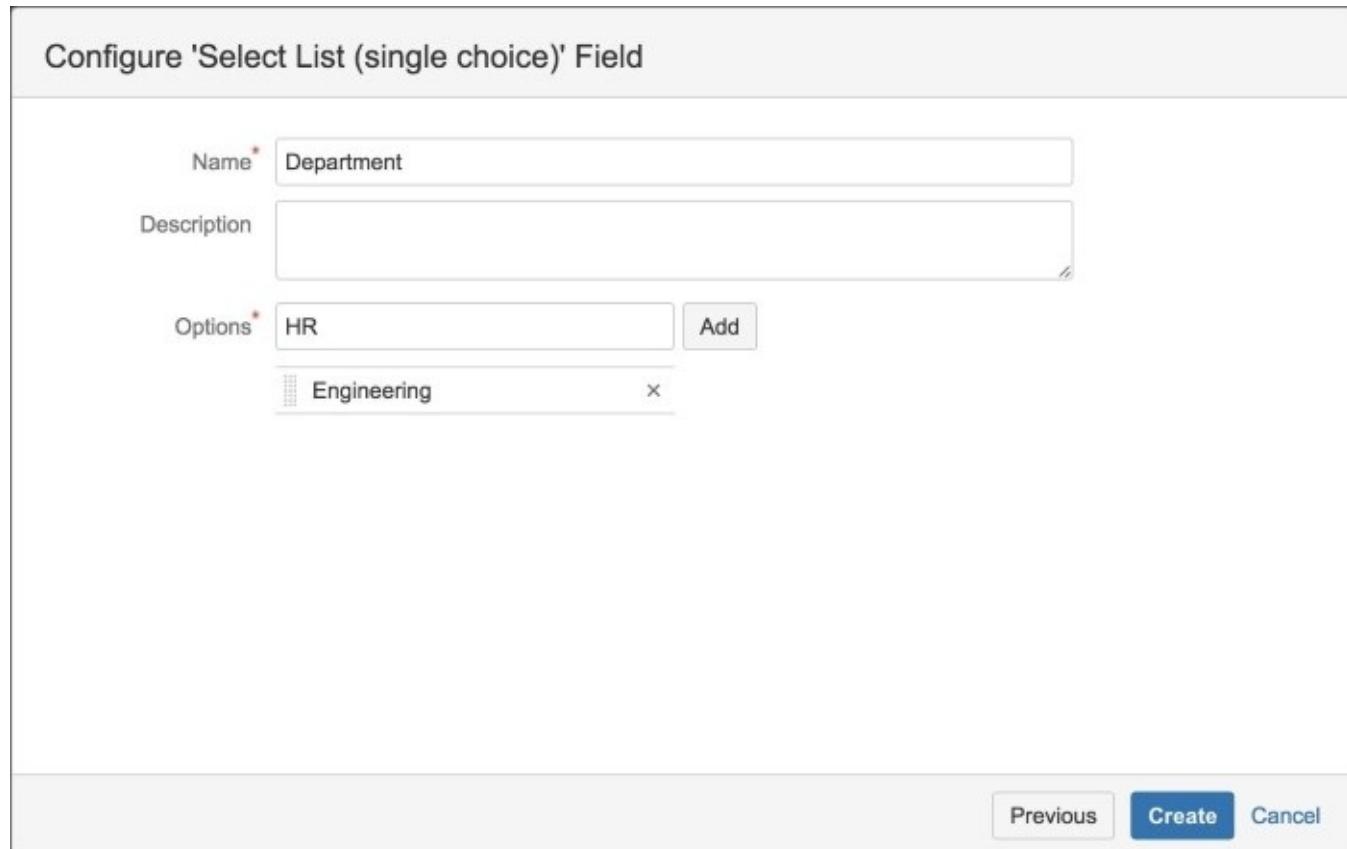

Name * Department

Description

Options * HR Add

Engineering x

Previous Create Cancel

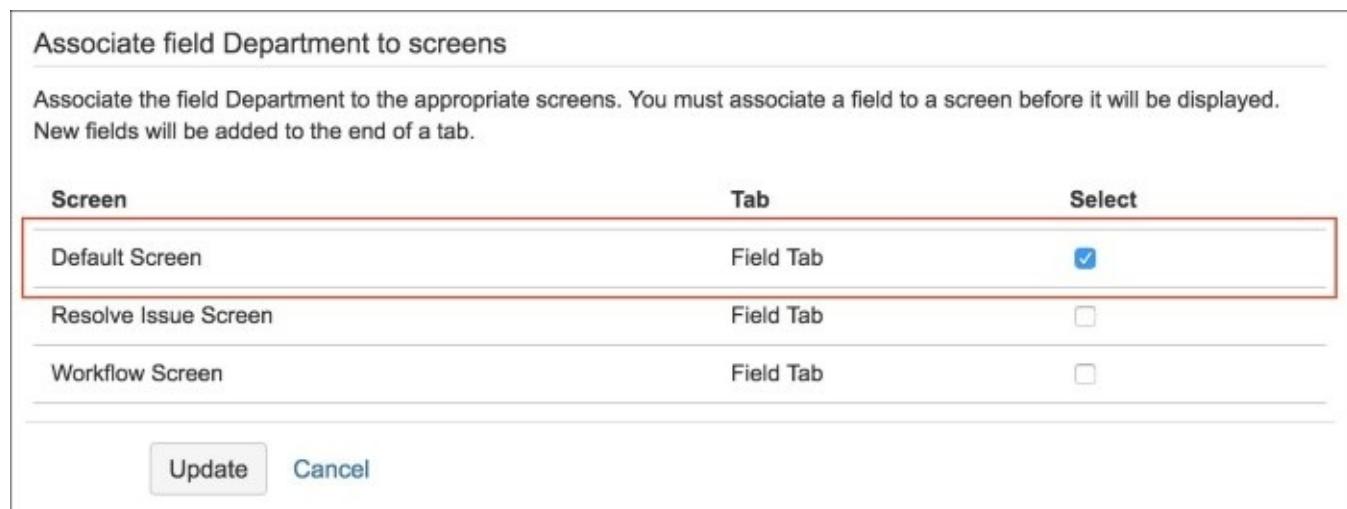

- Click on the **Create** button. This will bring you to the last step of the process, where you can specify which screen you would like to add the field onto. This step is optional as the custom field has already been added in JIRA. You do not have to add the field onto a screen. We will discuss fields and screens in [Chapter 6, Screen Management](#).
- Select the screens and click on **Update**. The following screenshot shows that the newly created field is added to **Default Screen**:

Associate field Department to screens

Associate the field Department to the appropriate screens. You must associate a field to a screen before it will be displayed. New fields will be added to the end of a tab.

Screen	Tab	Select
Default Screen	Field Tab	<input checked="" type="checkbox"/>
Resolve Issue Screen	Field Tab	<input type="checkbox"/>
Workflow Screen	Field Tab	<input type="checkbox"/>

Update Cancel

Once a custom field has been created, you will see it on the appropriate screen when you are creating, editing, or viewing issues.

Editing/deleting a custom field

Once a custom field has been created, you can edit its details at any time. You may already notice that there is a **Configure** option and an **Edit** option for each custom field. It can be confusing in the beginning to differentiate between the two. Configure specifies options related to the custom field context, which we will discuss in the following sections. Edit specifies options that are global across JIRA for the custom field; these include its name, description, and search templates:

1. Browse to the **Custom Fields** page.
2. Select the **Edit** option by clicking on the cog icon for the custom field you wish to edit from the list of custom fields.
3. Change the custom field details, such as its name or search template.
4. Click on the **Update** button to apply the changes.

When making changes to the search templates for your custom fields, it is important to note that while the change will take effect immediately, you need to perform a full system re-index in order for JIRA to return the correct search results. This is because for each search template, the underlying search data structure may be different, and JIRA will need to update its search index for the newly applied search template.

For example, if you have a custom field that did not have a searcher and you just applied a searcher to it, no results will be returned until you re-index JIRA. When you make changes to the search template, JIRA will alert you with a message that a re-index will be required, as shown in the following screenshot:

JIRA admin

Add-ons User management System

Edit Custom Field Details

If the search template is changed, manual reindexing must follow

Field Name Department

Description

A description of this particular custom field.
You can include HTML, make sure to close all your tags.

Search Template Multi Select Searcher

Note that changing a custom field searcher may require a re-index.

Update Cancel

Tip

You should select the background re-index option to avoid any downtime.

We will discuss searching and indexing in more detail in [Chapter 10, Searching, Reporting, and Analysis](#).

You can also delete the existing custom fields, as follows:

1. Browse to the **Custom Fields** page.
2. Select the **Delete** option by clicking on the tools icon for the custom field you wish to delete.
3. Click on the **Delete** button to delete the custom field.

Once deleted, you cannot get the custom field back, and you will not be able to retrieve and search the data held by those fields. If you try to create another custom field of the same type and name, it will not inherit the data from the previous custom field, as JIRA assigns unique identifiers to each of them. It is highly recommended to back up your JIRA project before you delete the field.

Configuring a custom field

Now that we have seen how to create and manage custom fields, we can start looking at more advanced configuration options. Different custom field types will have different configuration options available to them. For example, while all the custom fields will have the option to specify one or more contexts, the selection list-based custom fields will also allow you to specify a list of options. We will look at each of the configuration options in the following sections.

To configure a custom field, you need to access the **Configure Custom Field** page, as follows:

1. Browse to the **Custom Fields** page.
2. Select the **Configure** option by clicking on the cog icon for the custom field you wish to configure from the list of custom fields. This will bring you to the **Configure Custom Field** page.

The following screenshot shows that the **Department** custom field has two available contexts, the default context **Default Configuration Scheme**, which is applied to all projects (except **Help Desk**), and **Help Desk Configuration Scheme**, which is applied only to the **Help Desk** project:

Configure Custom Field: Department

Below are the Custom Field Configuration schemes for this custom field. Schemes are applicable for various issues types in a particular context. You can configure a custom field differently for each project context or in a global context. Moreover, project level schemes will over-ride global ones.

Options: [Edit Options](#)

- HR
- PMO

Adding custom field contexts

From time to time, you may need your custom fields to have different behaviors depending on what project the issue is in. For example, if we have a select list custom field called **Department**, we may want it to have a different set of options based on which project the issue is being created in, or even a different default value.

To achieve this level of customization, JIRA allows you to create multiple custom field contexts for a custom field. As we have seen already, a custom field context is a combination of issue types and projects. Therefore, in our example, we can create a context for the **Task** issue type and the **Help Desk** project and set the default department to **PMO**.

Note

JIRA allows you to configure custom fields based on issue types and projects through contexts. Each project can have only one configuration context per custom field.

Creating a new custom field context is simple. All you need to do is decide the issue type and project combination that will define the context:

1. Browse to the **Configure Custom Field** page for the custom field you wish to create a new context for.
2. Click on the **Add new context** link. This will take you to the **Add configuration scheme context** page.
3. Enter a name to the new custom field context in the **Configuration scheme** label field.
4. Select the issue types for the new context under the **Choose applicable issue types** section.
5. Select the projects for the new context under the **Choose applicable context** section.
6. Click on the **Add** button to create the new custom field context.

Each project can only belong to one custom field context per custom field (global context is not counted for this). Once you select a project for context, it will not be available the next time you create a new context. For example, if you create a new context for Project A, it will not be listed as an option when you create another context for the same custom field. This is to prevent you from accidentally creating two contexts for the same project.

After a new custom field context has been created, it will not inherit any configuration values as the default context such as **Default Value** and **Select Options** from other contexts. You will need to repopulate and maintain the configuration options for each newly created context.

Configuring select options

For custom field types, select the list, checkboxes, radio buttons, and their multi-versions. You need to configure their select options before they can become useful to the users. The select options are configured and set on a per custom field context basis. This provides the custom field with the flexibility of having different select options for different projects.

To configure the select options, you need to first select the custom field and then the context that the options will be applied to, as follows:

1. Browse to the **Custom Fields** page.
2. Click on the **Configure** option for the custom field you wish to configure the select options for.
3. Click on the **Edit Options** link for the custom field context to apply the options to.
4. Enter the option values in the **Add New Custom Field Option** section, and click on the **Add** button to add the value. The options will be added in the order in which they are entered into the system. You can manually move the option values up and down or click on **Sort options alphabetically** to let JIRA perform the sorting for you.
5. Click on the **Done** button once you finish configuring the select options:

Edit Options for Custom Field : Department

Reorder the option list below or add a new option for config Default Configuration for Department for custom field Department

- Sort options alphabetically
- View Custom Field Configuration

2.	Sales	↑ ↗ ↓ ↘	<input type="checkbox"/>	Edit · Delete · Disable
3.	P&T	↑ ↗	<input type="checkbox"/>	Edit · Delete · Disable

Move

Add New Custom Field Option

Add Value

Add **Done**

Setting default values

For most custom fields, you can set a default value so your users will not need to fill them unless they have special needs. For text-based custom fields, the default values will be displayed as text by default, when the users create or edit an issue. For selection-based custom fields, the default values will be preselected options for the users.

Just like setting selection options, default options are also set on a per custom field context basis:

1. Browse to the **Custom Fields** page.
2. Click on the **Configure** option for the custom field you wish to configure the select options for.
3. Click on the **Edit Default Value** link for the custom field context to apply the default values to.
4. Set the default value for the custom field.
5. Click on the **Set Default** button to set the default value.

Setting the default value will be different for different custom field types. For text-based custom fields, you will be able to type any text string. For select-based custom fields, you will be able to select from the options you add. For picker-based custom fields such as User Picker, you will be able to select a user directly from the user base.

Field configuration

As you have already seen, fields are used to capture and display data in JIRA. Fields can also have behaviors, which are defined by field configuration. For each field in JIRA, you can configure its behaviors listed as follows:

- **Field description:** This is the description text that appears under the field when an issue is edited. With field configuration, you can have different description texts for different projects and issue types.
- **Visibility:** This determines if a field should be visible or hidden.
- **Required:** This specifies if a field will be optional or required to have a value when an issue is being created/updated. When applied to a select, checkbox, or radio button custom fields, this will remove the **None** option from the list.
- **Rendering:** This specifies how the content is to be rendered for text-based fields (for example, wiki renderer or simple text renderer for text fields).

A field configuration provides you with control over each individual field in your JIRA, including both built-in and custom fields. Since it is usually a good practice to reuse the same set of fields instead of creating new ones for every project, JIRA allows you to create multiple field configurations, with which we can specify different behaviors on the same set of fields and apply them to different projects.

We will be looking at how to manage and apply multiple field configurations in the later sections of this chapter. But first, let's take a close look at how to create new field configurations and what we can do with them.

You can access the field configuration management page through the JIRA administration console:

1. Browse to the JIRA administration console.
2. Select the **Issues** tab and then the **Field configurations** option. This will bring you to the **View Field Configurations** page.

Adding a field configuration

Creating new field configurations is simple. All you need to do is specify the name and the short description for the new configuration:

1. Browse to the **View Field Configurations** page.
2. Click on the **Add Field Configuration** button.
3. Enter the name and description for the new field configuration.
4. Click on the **Add** button to create a field configuration.

As we will see later in the *Field Configuration Scheme* section, field configurations are linked to issue types, so it is recommended to name them based on the issue type they will be applied to and with a version number at the end, for example, Bugs Field Configuration 1.0. This way, when you need to make changes to the field configuration, you can increment the version number, leaving a history of changes you can revert to.

After a field configuration is created, it is not put to use until we associate it with a field configuration scheme. We will look at how to do this in later sections.

Managing field configurations

Now that we have seen how to create new field configurations, it is time for us to take a closer look at the different configuration options. Just a quick recap - each field configuration includes all the fields available in JIRA, and its behavior is defined specifically to each field configuration. We will then associate it with a field configuration scheme, which will determine when a field configuration will become active for a given issue.

Perform the following steps to access the field configuration options:

1. Browse to the **View Field Configurations** page.
2. Click on the **Configure** link for the field configuration you wish to configure. This will take you to the **View Field Configuration** page.

On this page, all the fields and their current configuration options that are currently set for the selected field configuration are listed:

View Field Configuration			
The table below shows all fields configured in JIRA and their properties for Epic Field Configuration .			
Name	Screens	Operations	
Affects Version/s REQUIRED field is mandatory [Autocomplete Renderer]	<ul style="list-style-type: none">Default Screen	Edit · Hide · Optional Screens · Renderers	
Assignee	<ul style="list-style-type: none">Default ScreenResolve Issue ScreenWorkflow Screen	Edit · Show field is hidden	
Attachment	<ul style="list-style-type: none">Default Screen	Edit · Hide · Screens	
Comment [Wiki Style Renderer]	This field can not be placed on screens by users.	Edit · Renderers	

As you can see, there are several options you can configure for each field, and depending on the field type, the options may vary. While we will be looking at each of the options, it is important to note that some of the options will override each other. This is JIRA trying to protect you from accidentally creating a configuration combination that will break your system. For example, if a field is set to both hidden and required, your users will not be able to create or edit issues, so JIRA will not allow you to set a field to required if you have already set it to hidden.

Field description

While having a meaningful name for your fields will help your users understand what the fields are for, providing a short description will provide more context and meaning. Field descriptions are displayed under the fields when you create or edit an issue. To add a description for a field, do the following:

1. Browse to the **View Field Configuration** page for the field configuration you wish to use.
2. Click on the **Edit** link for the field you wish to set a description for.
3. Add a description for the field, and click on **Update**.

Note

For custom fields, the description you enter here will override the description you provide when you first create them.

Field requirement

You can set certain fields as required or mandatory for issues. This is a very useful feature as it ensures that critical information can be captured when users create issues. For example, for our support system, it makes sense to have our users enter in the system that is misbehaving in a field and make that field compulsory to help our support engineers.

You have already seen required fields in action. System fields, such as **Summary** and **Issue Type**, are compulsory in JIRA (and you cannot change that). When you do not specify a value for a required field, JIRA will display an error message underneath the field, telling you that the value is required.

When you add a new field into JIRA, such as custom fields, it is optional by default, meaning users do not need to specify a value. You can then change the setting to make those fields required:

1. Browse to the **View Field Configuration** page for the field configuration you wish to use.
2. Click on the **Required/Optional** link for the field you wish to set as the mandatory requirement.

You will notice that once a field is set to required, there will be a small required text label in red next to the field name. When you create or edit an issue, the field will have a red * character next to its name. This is JIRA's way of indicating that a field is mandatory.

Field visibility

Most fields in JIRA can be hidden from user's view. When a field is set to hidden, users will not see the fields on any screens, including issues such as create, update, and view. Perform the following steps to show or hide a field:

1. Browse to the **View Field Configuration** page for the field configuration you wish to use.
2. Click on the **Show/Hide** link for the field you wish to show or hide, respectively.

Once a field has been set to hidden, it will not appear on screen and you will not be able to search in it. However, you can still use tools such as scripts to set values for hidden fields. For this reason, hidden fields are used to store data that is used by automated processes.

Not all fields can be hidden. Built-in fields, such as `Summary` and `Issue Type`, cannot be hidden. When you set a field to hidden, you will notice that you can no longer set the field as required. As stated earlier, setting a field to required will make JIRA enforce a value to be entered into the field when you create or edit an issue. If the field is hidden, there will be no way for you to set a value and you will be stuck. This is why JIRA will automatically disable the required option, especially if you have already hidden a field. On the other hand, if you marked a field as required, when you hide the same field, you will notice that the field is no longer required. The rule of thumb is that field visibility will override field requirement.

Note

A field cannot be both hidden and required.

Field rendering

Renderers control how a field will be displayed when it is being viewed or edited. Some built-in and custom fields have more than one renderer, and for these fields, you can choose which one to use. For example, for text-based fields, such as **Description**, you can choose to use the simple text renderer or the more sophisticated wiki-style renderer that will allow you to use wiki markup to add more styling.

JIRA ships with four different renderers:

- **Default text renderer:** This is the default renderer for text-based fields. Contents are rendered as plain text. If the text resolves a JIRA issue key, the renderer will automatically turn that into an HTML link.
- **Wiki style renderer:** This is an enhanced renderer for text-based fields. It allows you to use wiki markup to decorate your text content.
- **Select list renderer:** This is the default renderer for selection-based fields. It is rendered as a standard HTML select list.
- **Autocomplete renderer:** This is an enhanced renderer for selection-based fields, and it provides an autocomplete feature to assist users as they start typing into the fields.

The following table lists all the fields that can have special renders configured and their available options:

Field	Available renderers
Description	This is a wiki-style renderer and default text renderer.
Comment	This is a wiki-style renderer and default text renderer.
Environment	This is a wiki-style renderer and default text renderer.
Component	This is an autocomplete renderer and select list renderer.
Affects version	This is an autocomplete renderer and select list renderer.
	This is an autocomplete renderer and select

Fix versions	list renderer.
Custom field of type Free Text Field (unlimited text)	This is a wiki-style renderer and default text renderer.
Custom field of type Text Field	This is a wiki-style renderer and default text renderer.
Custom field of type Multi Select	This is an autocomplete renderer and select list renderer.
Custom field of type Version Picker	This is an autocomplete renderer and select list renderer.

Perform the following steps to set the renderer for a field:

1. Browse the **View Field Configuration** page for the field configuration you wish to use.
2. Click on the **Renderer** link for the field you wish to set a renderer for (if it is available). You will be taken to the **Edit Field Renderer** page.
3. Select the renderer from the available drop-down list.
4. Click on the **Update** button to set the renderer.

There are other custom renderers developed by third-party vendors. Just like custom fields, these are packaged as add-ons that you can install in JIRA. Once installed, these custom renderers will be available for the selection of the appropriate field types.

A good example is the **JEditor** plugin, which provides a rich-text editor for all text-based fields such as **Description**.

Screens

In order for a field to be displayed when you view, create, or edit an issue, it needs to be placed onto a screen. You have already seen this when creating new custom fields. One of the steps in the creation process is to select what screens to add the custom field to. Screens will be discussed further in [Chapter 6, Screen Management](#), so we will not spend too much time understanding them right now.

What you need to know for now is that after a field has been added to a screen, you can add it to additional screens or take it off completely. If you are working with just one field, you can configure it here from the field configurations. If you have multiple fields to update, a better approach will be to work directly with screens, as we will see in [Chapter 6, Screen Management](#).

There is a subtle difference between hiding a field in field configuration and not placing a field on a screen. While the end result will be similar where in both cases the field will not show up, if you hide a field, you can still set a value for it through the use of default value, workflow post-functions (covered in [Chapter 7, Business Process and Workflow](#)), or custom scripts, essentially meaning the field is there but just hidden. However, if the field is not on the screen, you cannot set its value, and can be considered the field is not part of the issue. Another difference is hiding a field will hide it for all screens that have the field added, for projects using the field configuration.

Field configuration scheme

With multiple field configurations, JIRA determines when to apply each of the configurations through the field configuration scheme. A field configuration scheme maps field configurations to issue types. This scheme can then be associated with one or more projects.

This allows you to group multiple field configurations mapped to issue types and apply them to a project in one go. The project will then be able to determine which field configuration to apply, based on the type of the issue. For example, for a given project, you can have different field configurations for bugs and tasks.

This grouping of configurations into schemes also provides you with the option to reuse existing configurations without duplicating work, as each scheme can be reused and associated with multiple projects.

Managing field configuration schemes

You can manage all your field configuration schemes from the **View Field Configuration Schemes** page. From there, you will be able to add, configure, edit, delete, and copy schemes:

1. Browse to the JIRA administration console.
2. Select the **Issues** tab and then the **Field Configuration Schemes** option. This will bring you to the **View Field Configuration Schemes** page:

View Field Configuration Schemes

+ Add Field Configuration Scheme ?

The table below shows the current Field Configuration Schemes and the projects they are associated with.

ⓘ Field Configuration Schemes map Field Configurations to issue types. A Field Configuration Scheme can be associated with one or more projects, making issues in these projects use the Field Configuration mapped to their issue type.

Name	Projects	Operations
Engineering Field Configuration Scheme Field configuration scheme for engineering projects.		Configure · Copy · Edit · Delete
Support Field Configuration Scheme Field configuration scheme for support team projects.	• Help Desk	Configure · Copy · Edit

Adding a field configuration scheme

The first step to group your field configurations is to create a new field configuration scheme. By default, JIRA does not come with any field configuration schemes. All the projects will use the system default field configuration. The new field configuration scheme will hold all the mappings between our field configurations and issue types.

To create a new field configuration scheme, all you need to do is specify the name and an optional description for the scheme:

1. Browse to the **View Field Configuration Schemes** page.
2. Click on the **Add Field Configuration Scheme** button.
3. Enter a name and description for the new field configuration scheme.
4. Click on the **Add** button to create the scheme.

Since field configuration schemes are applied to projects, it is a good practice to name them according to the projects. For example, the scheme for the sales project can be named **Sales Field Configuration Scheme**. You can add a version number after the name to help you maintain changes.

Once the new field configuration scheme is created, it will be displayed in the table that lists all the existing schemes. At this time, the scheme is not yet useful as it does not contain any configuration mappings and is associated with a project.

Configuring a field configuration scheme

Once you have a new field configuration scheme set up, you will be able to add mapping between field configurations and issue types. For each field configuration scheme, one issue type can be mapped to only one field configuration, while each field configuration can be mapped to multiple issue types. The following screenshot shows **Task Field Configuration** is applied to both the **Task** issue type, and also **Default Field Configuration** is applied to all issue types that do not have an explicit mapping:

Configure Field Configuration Scheme: Support

Field Configuration Scheme

+ Associate an Issue Type with a Field Configuration

This scheme can be used by one or more projects, the field configuration specified for each issue type will be applied to the issues in these projects.

The *Default* entry specifies the field configuration that will be used for any issue type that has not been explicitly mapped to a field configuration.

[View all field configuration schemes.](#)

Issue Type	Field Configuration	Operations
Default Used for all unmapped issue types.	Default Field Configuration	Edit
Story	Story Field Configuration	Edit · Delete
Task	Task Field Configuration	Edit · Delete
Epic	Epic Field Configuration	Edit · Delete

Note

One issue type can only be mapped to one field configuration.

When a field configuration scheme is first created, JIRA creates a default mapping, which maps all unmapped issue types to the default field configuration. You cannot delete this default mapping as it acts as a catch-all condition for mappings that you do not specify in your scheme. What you need to do is add more specific mappings that will take precedence over this default mapping:

1. Browse to the **View Field Configuration Schemes** page.
2. Click on the **Configure** link for the field configuration scheme you wish to configure.
3. Click on the **Associate an Issue Type with a Field Configuration** button.
4. Select the issue type and field configuration from the dialog.

5. Click on the **Add** button to add the mapping.

You can repeat these steps to add more mapping for other issue types. All unmapped issue types will use the **Default** mapping.

Associating a field configuration scheme with a project

After you create a new field configuration scheme and establish the mappings, the last step is to associate the scheme with a project for the configurations to take effect.

It is important to note that once you associate the field configuration scheme with a project, you cannot delete it until you remove all the associations so the scheme becomes inactive again.

To associate a field configuration scheme with a project:

1. Browse to the target project's administration page.
2. Click on the **Fields** option in the left panel.
3. Select the **Use a different scheme** option from the **Actions** menu.
4. Select the new field configuration scheme and click on the **Associate** button.

As shown in the following screenshot, the project is using the **Support Field Configuration Scheme**, which has two configurations:

- The **Task** issue type is using **Task Field Configuration**.
- All other issue types such as **Sub-task** are using the **Default Field Configuration**:

The screenshot shows the Jira Fields configuration page for the "Support Field Configuration Scheme". At the top, there is a "Fields" icon and the title "Support Field Configuration Scheme". Below the title, a message states: "Different issues can have different information fields. A field configuration defines how fields behave for the project: required/optional; hidden/visible." To the right, there is a "Actions" dropdown menu with options "Edit fields" and "Use a different scheme", where "Use a different scheme" is highlighted. The main content area displays two field configurations:

- "Default Field Configuration" (Sub-task): This section shows a list of fields for the "Sub-task" issue type. There is a pencil icon to the right of the list.
- "Task Field Configuration" (Task, DEFAULT): This section shows a list of fields for the "Task" issue type, with "DEFAULT" selected. There is a pencil icon to the right of the list.

Tip

You can click on each of the field configurations to view their details.

The HR project

Now that you have seen how to manage fields in JIRA, it is time to expand on our HR project. What we will do this time is add a few new custom fields to help capture some additional useful information. We will also create a customized field configuration specially designed for our HR team. Lastly, we will tie everything together by associating our fields, configurations, and projects through the field configuration schemes.

Setting up a custom field

Since you are implementing a project for HR, and we have created two issue types in the last chapter, **New Employee** and **Termination**. For the **New Employee** issue type, we will add a new custom field called **Direct Manager**, so when everything is completed, the manager can be notified that his/her new team member is ready to start. Since the manager is already in the organization, we will be using a user picker field, so JIRA will be able to automatically look up the user for us.

For our **Termination** issue type, we will also add a new custom field called **Last Day**, so we know when it will be the last day for the employee. For this field, we will use a date picker, so we can keep the date format consistent.

To create these custom fields:

1. Browse to the **View Custom Fields** page.
2. Click on the **Add Custom Field** button.
3. Select the **User Picker** custom field type.
4. Name the custom field **Direct Manager** and click on **Create**.
5. Select **HR: Task Management Create Issue Screen** and **HR: Task Management Edit/View Issue Screen**, and click on **Update**.
6. Repeat steps 2 to 5, but select the **Date Picker** field type and call it **Last Day**.

Setting up the field configuration

Now that we have our custom fields ready, the next step is to create a new field configuration so that we can specify the behaviors of our custom fields. What we will do here is to set both new custom fields as required, so when the issues are entered in JIRA, users will have to enter a value for them. But the **Direct Manager** field should only be required when creating a **New Employee** issue, and not **Termination**. To do this, we need to create two field configurations:

1. Browse to the **View Field Configurations** page.
2. Click on the **Add Field Configuration** button.
3. Name the new field configuration **New Employee Field Configuration**.
4. Click on the **Add** button to create a new field configuration. Now that we have our new field configuration, we can start adding configurations to our new custom fields.
5. Click on the **Required** link for the **Direct Manager** custom field.
6. Repeat Steps 2 to 5 to create a new **Termination Field Configuration**, and make the **Last Day** field mandatory.

Setting up a field configuration scheme

We have our custom fields, have configured the relevant options, created a new field configuration, and set the behavior of our fields. It is time to add them to a scheme:

1. Browse to the **View Field Configuration Schemes** page.
2. Click on the **Add Field Configuration Scheme** button.
3. Name the new field configuration scheme **HR Field Configuration Scheme**, as we will be applying this to our HR project.
4. Click on the **Add** button to create a new field configuration scheme.

With the field configuration scheme created, we can associate the field configurations to their appropriate issue types, **New Employee** and **Termination**:

1. Click on the **Associate an Issue Type with a Field Configuration** button.
2. Set the issue type as **New Employee** and the field configuration as **New Employee Field Configuration**.
3. Click on the **Add** button to add the association.
4. Repeat steps 1 to 3 for the **Termination** issue type and **Termination Field Configuration**.

Putting it together

OK, we have done all the hard work. We created new custom fields, a new field configuration, and a new field configuration scheme; the last step is to put everything together and see it in action:

1. Browse to the **Project Administration** page for our HR project.
2. Click on the **Fields** link on the left-hand side and the **Use a different scheme** option from the **Actions** menu.
3. Select **HR Field Configuration Scheme** and click on the **Associate** button.

Alright, we are all done! You can pat yourself on the back, sit back, and take a look at your hard work in action.

Create a new issue of type New Employee in the HR project, and you will see your new custom fields at the bottom of the page. As shown in the following screenshot, the **Direct Manager** field is mandatory and an error message is displayed if we do not select a value for it, while the **Last Day** field is optional:

Create Issue Configure Fields ▾

✉ ⓘ

Assignee: Automatic ⓘ

Assign to me

Priority: Medium ⓘ

Labels: ⓘ

Begin typing to find and create labels or press down to select a suggested label.

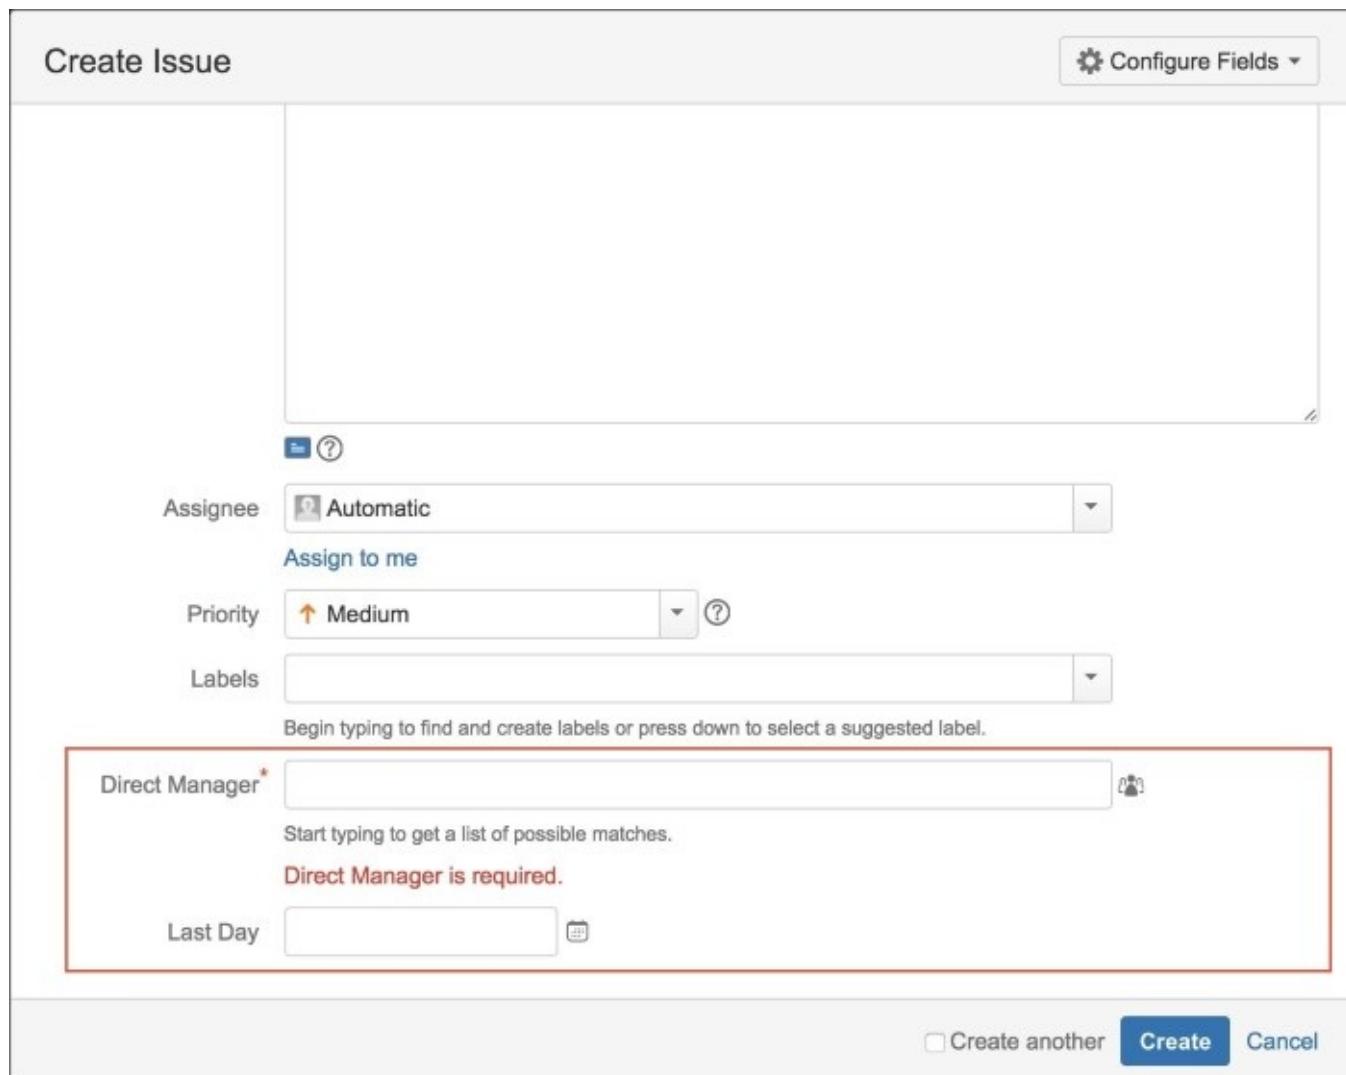

Direct Manager* ⓘ

Start typing to get a list of possible matches.

Direct Manager is required.

Last Day ⓘ

Create another Create Cancel

Note

We are seeing both **Direct Manager** and **Last Day** custom fields here because both **New Employee** and **Termination** issue types use the same set of screens. We will look at how to use separate screens in the next chapter. We can, however, also use field configuration to hide the field for the appropriate issue type.

Go ahead and create **New Employee** by filling in the fields. On the **View Issue** page, you will see your new custom fields displayed, along with the values you provide:

The screenshot shows a Jira issue view for a New Employee named Mike Johnson. The issue key is HR-1. The top navigation bar includes 'Edit', 'Comment', 'Assign', 'More', 'Done', and 'Admin' buttons, along with 'Export' options. The main area is divided into 'Details' and 'People' sections. In the 'Details' section, there are fields for Type (New Employee), Priority (Medium), Labels (None), Status (TO DO), Resolution (Unresolved), and a 'Description' field containing the text 'We have a new employee joining us.' A red box highlights the text 'our custom field' in the description. In the 'People' section, it lists Assignee (John Stein), Reporter (patrick@appfusions.com), Direct Manager (Kim Lee), Votes (0), and Watchers (Stop watching this issue).

Details		People	
Type:	New Employee	Assignee:	John Stein
Priority:	Medium	Reporter:	patrick@appfusions.com
Labels:	None	Direct Manager:	Kim Lee
Description		Votes:	0
We have a new employee joining us.		Watchers:	Stop watching this issue

Summary

In this chapter, we looked at fields in JIRA. We also looked at how JIRA is able to extend its ability to capture user data through custom fields. We explored how we can specify different behavior for fields under different contexts through the use of field configurations and schemes.

In the next chapter, we will expand on what we learned about fields by formally introducing you to screens, and how combining fields and screens provide users with the most natural and logical forms to assist them with creating and logging issues.

Chapter 6. Screen Management

Fields collect data from users, and you have seen how to create your own custom fields from a wide range of field types to address your different requirements. Indeed, data collection is at the center of any information system, but that is only half of the story. How data is captured is just as critical. Data input forms need to be organized so that users do not feel overwhelmed, and the general flow of fields needs to be logically structured and grouped into sections. This is where screens come in.

In this chapter, we will pick up where we left off in the last chapter and explore the relationship between fields and screens. We will further discuss how you can use screens to customize your JIRA to provide users with a better user experience. By the end of the chapter, you will learn the following:

- What screens are and how to create them
- How to add fields onto screens
- How to break down your screen into logical sections with tabs
- The relationship between screens and issue operations
- How to link screens with projects and issue types

JIRA and screens

Before you can start working with screens, you need to first understand what they are and how they are used in JIRA.

Compared to a normal paper-based form, fields in JIRA are like the check-boxes and spaces that you have to fill in, and screens are like the form documents themselves. When fields are created in JIRA, they need to be added to screens in order to be presented to users. Therefore, you can say that screens are like groupings or containers for fields.

In most cases, screens need to be associated with issue operations through what are known as screen schemes. Screen schemes map screens to operations, such as creating, viewing, and editing issues, so that you can have different screens for different operations. Screen schemes are then associated with issue type screen schemes, which when applied to projects will map screen schemes to issue types. This lets each issue type in a project have its own set of screens. The only time when a screen will be used directly is when it is associated with a workflow transition. In JIRA, a workflow defines the various statuses an issue can go through; for example, an issue can go from open to close. Transitions are the actions that take the issue from one status to the next, and JIRA lets you display a screen as part of the action if you choose to. We will cover workflows in [Chapter 7, Workflows and Business Processes](#).

To help you visualize how screens are used in JIRA, Atlassian has provided the following figure that summarizes the relationship between fields, screens, and their respective schemes:

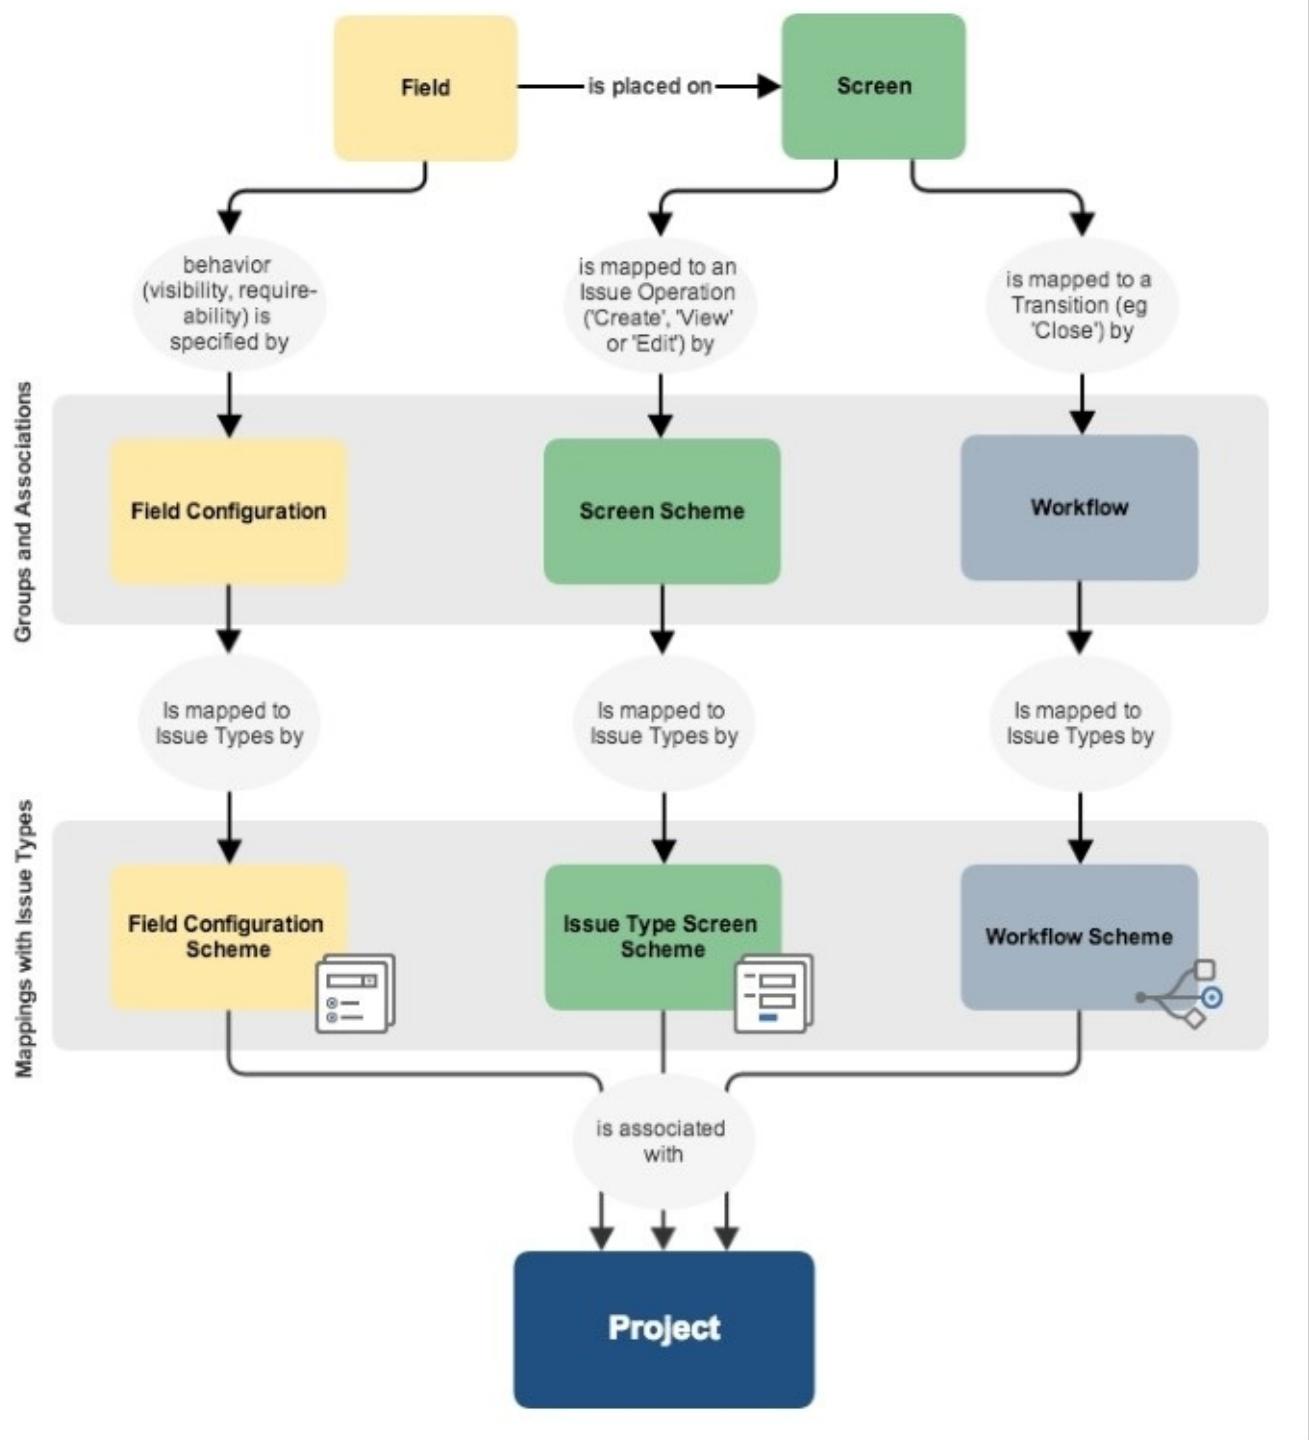

Image source: <https://confluence.atlassian.com/adminjiraserver071/project-screens-schemes-and-fields-802592517.html>

Working with screens

While many other software systems provide users with limited control over the presentation of screens, JIRA is very flexible when it comes to screen customizations. You can create your own screens and decide what fields are to be placed on them and their orders. You can also decide which screens are to be displayed for major issue operations. In JIRA, you can create and design customized screens for the following operations:

- Create an issue in the create issue dialog box
- Edit an issue when an issue is being updated
- View an issue after an issue is created and is being viewed by users
- Manage workflows during workflow transitions (workflows will be covered in [Chapter 7, Workflows and Business Processes](#))

Screens are maintained centrally from the administration console, which means you need to be a JIRA administrator to create and configure screens. Perform the following steps to access the **View Screens** page:

1. Log in as a JIRA administrator user.
2. Browse to the JIRA administration console.
3. Select the **Issues** tab and then the **Screens** option; this will bring up the **View Screens** page.

The **View Screens** page lists all the screens that are currently available in your JIRA instance. You can select a screen and configure what fields will be on this screen and decide how you can divide a screen into various tabs.

For each of the screens listed here, JIRA will also tell you what screen scheme each of the screens are a part of and the workflows that are being used. You have probably noticed that for screens that are either part of a screen scheme or workflow, there is no **Delete** option available, as you cannot delete screens that are in use. You need to disassociate the screen from screen schemes and/or workflows to delete them, as shown in the following screenshot:

View Screens

[+ Add Screen](#)

A screen is an arrangement of fields that are displayed when the issue is created, edited or transitioned through workflow.

- To choose screens that are displayed when issues are **created** or **edited** please map the screens to issue operations using Screen Schemes.
- To select which screen is displayed for a particular **workflow transition**, please select the workflow the transition belongs to and edit it.

Note: it is only possible to delete a screen if it is not part of a Screen Scheme and is not used in any workflows.

Name	Screen schemes	Workflows	Operations
Default Screen Allows to update all system fields.	• Default Screen Scheme		Configure · Edit · Copy
HD: Task Management Create Issue Screen	• HD: Task Management Screen Scheme		Configure · Edit · Copy
HD: Task Management Edit/View Issue Screen	• HD: Task Management Screen Scheme		Configure · Edit · Copy
Resolve Issue Screen Allows to set resolution, change fix versions and assign an issue.		• jira (Close Issue) • jira (Resolve Issue) • classic default workflow (Resolve Issue) • classic default workflow (Close Issue)	Configure · Edit · Copy
Workflow Screen This screen is used in the workflow and enables you to assign issues		• jira (Close Issue) • jira (Reopen Issue) • classic default workflow (Close Issue) • classic default workflow (Reopen Issue)	Configure · Edit · Copy

As shown in the preceding screenshot, for each screen you can perform the following operations:

- **Configure:** This configures what fields are to be placed on the screen. Not to be confused with the **Edit** operation.
- **Edit:** This updates the screen's name and description.
- **Copy:** This makes a copy of the selected screen, including its tabs and field configurations.
- **Delete:** This deletes the screen from JIRA. Only available if it is not being used by a screen scheme or workflow.

Note

Screens listed here do not affect JIRA Service Desk. We will cover screens and fields configuration for JIRA Service Desk in [Chapter 11, JIRA Service Desk](#).

Adding a new screen

JIRA comes with three screens by default (listed here), and, every time you create a new project, a new set of screens is created for the project, based on the template you select. These project-specific screens will all have their names starting with the project key, for example, HD: Task Management View Issue Screen, where HD is the project's key.

- **Default Screen:** This screen is used for creating, editing, and viewing issues
- **Resolve Issue Screen:** This screen is used when resolving and closing issues
- **Workflow Screen:** This screen is used when transitioning issues through workflows (if configured to have a screen, such as **Reopen Issue**)

While the default screens and screens automatically created for your projects are able to cover the most basic requirements, you will soon find yourself outgrowing them, and adjustments will need to be made. For example, if you want to keep certain fields read-only, such as priority, so that they cannot be changed after issue creation, you can achieve this by setting up different screens for creating and editing issues. Another example will be to have different create and edit screens for different issue types, such as bug and task. In these cases, you will need to create your own screen in JIRA using the following steps:

1. Browse to the **View Screens** page.
2. Click on the **Add Screen** button. This will bring up the **Add Screen** dialog box.
3. Enter a meaningful name and description for the new screen. It is a good idea to name your screen after its purpose, for example, HD: Bug Create Screen, to indicate that it is the screen to create new bug issues for project HD.
4. Click on the **Add** button to create the screen.

At this point, your new screen is blank with no fields in it. You will see in later sections how to add fields onto screens and put them to use.

Editing/deleting a screen

You can edit existing screens to update their details to help keep your configurations up to date and consistent. Perform the following steps to edit a screen:

1. Browse to the **View Screens** page.
2. Click on the **Edit** link for the screen you wish to update. This will take you to the **Edit Screen** page.
3. Update the name and description of the screen.
4. Click on the **Update** button to apply your changes.

To delete an existing screen, it must not be used by any screen schemes or workflows. If it is associated with a screen scheme or workflow, you will not be able to delete it. You will need to undo the association first. Perform the following steps to delete a screen:

1. Browse to the **View Screens** page.
2. Click on the **Delete** link for the screen you wish to remove. This will take you to the **Delete Screen** page for confirmation.
3. Click on the **Delete** button to remove the screen.

Note

By deleting a screen, you do not delete the fields that are on the screen from the system.

Copying a screen

Screens can be complicated with many fields ordered logically, so creating a new screen from scratch may not be the most efficient method if there is already a similar one available. Just like with many other entities in JIRA, you can make a copy of an existing screen, thus cutting down the time that would otherwise take you to re-add all the fields:

1. Browse to the **View Screens** page.
2. Click on the **Copy** link for the screen you wish to copy. This will take you to the **Copy Screen** page.
3. Enter a new name and description for the screen.
4. Click on the **Copy** button to copy the screen.

Configuring screens

Creating a new screen is like getting a blank piece of paper; the fun part is to add and arrange the fields on the screen. Fields in JIRA are arranged and displayed from top to bottom in a single column. You have full control of what fields can be added and in what order they can be arranged.

The only exception to this is for the **View** screen. When you are viewing an issue, fields are grouped together by type. For example, user fields such as reporter and assignee are displayed together on the top right-hand side of the page. Also note that for built-in fields such as **Summary** and **Issue type**, even if you take them off the screen, they will still be displayed when viewing an issue. For these fields, you cannot change their position on the screen.

JIRA also allows you to break your screens into tabs or pages within a form, and you can do all of this within a single configuration page. It is this level of flexibility combined with a simplicity that makes JIRA a very powerful tool.

Perform the following steps to configure an existing screen:

1. Browse to the **View Screens** page.
2. Click on the **Configure** link for the screen you wish to configure.

On this page, you can do the following:

- Add/remove fields onto the screen
- Arrange the order of the fields
- Create/delete tabs on the screen
- Move fields from one tab to another

Adding a field to a screen

When you first create a screen, it is of little use. In order for screens to have items to present to the users, you must first add fields onto the screens:

1. Browse to the **Configure Screen** page for the screen you wish to configure.
2. Select the fields you would like to add by typing in the field's name in the **Select Field ...** drop-down list. JIRA will auto match the field as you type, as shown in the following screenshot:

Configure Screen

This page shows the way the fields are organized on **Bug Create Screen** screen.

Note: when the screen is shown to the user only non-hidden fields that the user has permissions to edit will be actually displayed.

Field Tab Add Tab

Summary	Remove
Description	
Affects Version/s	
Fix Version/s	
Assignee	

Select Field ...

Select a field to add it to the screen.

Fields are added to the bottom of the list. You can reorder the list of fields by simply dragging them up and down.

Deleting a field from a screen

Fields can be taken off from a screen completely. When a field is taken off, the field will not appear when the screen is presented to the users. There is a subtle difference between deleting a field from a screen and hiding it (discussed in the previous chapter). Although both actions will prevent the field from showing up, by removing the field, issues will not receive a value for that field when they are created. This becomes important when a field is configured to have a default value. When the field is removed, the issue will not have the default value for the field; while if the field is simply hidden, the default value will be applied.

You will also need to pay close attention when deleting fields off a screen, as there is no confirmation dialog. Make sure that you do not delete required fields, such as summary, from a screen used to create new issues. As seen in [Chapter 4, Field Management](#), JIRA will prevent you from hiding fields that are marked as required, but JIRA does not prevent you from taking the required fields off the screen. Therefore, it is possible for you to end up in a situation where JIRA requires a value for a field that does not exist on the screen. This can lead to very confusing error messages for end users:

1. Browse to the **Configure Screen** page for the screen you wish to configure.
2. Hover your mouse over the field you want to delete and click on the **Remove** button.

Note

When you delete a field from a screen, existing issues will not lose their values for the field. Once you add the field back, the values will be displayed again.

Using screen tabs

For most cases, you will be sequentially adding fields to a screen and users will fill them from top to bottom. However, there will be cases where your screen becomes over complicated and cluttered due to the sheer number of fields you need, or you simply want to have a way to logically group several fields together and separate them from the rest. This is where tabs come in.

If you think of screens as the entire form a user must fill in, then tabs will be individual pages or sections that make up the whole document. Tabs go from left to right, so it is a good practice to design your tabs to flow logically from left to right. For example, the first tab can gather general information, such as summary and description. Subsequent tabs will gather more domain-specific information:

Create Issue

Configure Fields ▾

Project* Demonstration Project (DEMO)

Issue Type* Bug ?

Field Tab Build Info Internal Only screen tabs

Summary*

Reporter* patrick@appfusions.com

Start typing to get a list of possible matches.

Adding a tab to a screen

You can add tabs to any screen in JIRA. In fact, by default, all screens have a default tab called **Field Tab** that is used to host all the fields. You can add new tabs to a screen to break down and better manage your screen presentation:

1. Browse to the **View Screens** page.
2. Click on the **Configure** link for the screen you wish to add a new tab for.
3. Click on the **Add Tab** link and enter a name for the tab.
4. Click on the **Add** button to create the tab.

Tabs are organized horizontally from left to right. When you add a new tab to the screen, they are appended to the end of the list. You can change the order of tabs by dragging them left and right in the list, as shown in the following screenshot:

The screenshot shows the 'Configure Screen' interface for the 'DEMO: Scrum Bug Screen' screen. At the top, there's a header with 'Configure Screen' and a help icon. Below it, a 'SHARED BY 1 PROJECT' badge. A note states: 'This page shows the way the fields are organized on DEMO: Scrum Bug Screen screen.' Another note says: 'Note: when the screen is shown to the user only non-hidden fields that the user has permissions to edit will be actually displayed.' The main area contains several tabs: 'Field Tab' (selected), 'Build Info', 'Internal Only' (with edit and delete icons), and 'Add Tab'. Below the tabs is a list of fields: 'Department', 'Direct Manager', 'Last Day', 'Epic Name', and 'Log Work'. At the bottom, there's a dropdown menu labeled 'Select Field ...' and a note: 'Select a field to add it to the screen.'

You can also move a field from one tab to another by dragging the field and hovering it over to the target tab. This will save you some time having to manually remove a field from a tab and then add it to the new tab.

Editing/deleting a tab

Just like screens, you can maintain existing tabs by editing their names and/or removing them from the screen. Perform the following steps to edit a tab's name:

1. Browse to the **View Screens** page.
2. Click on the **Configure** link for the screen that has the tab you wish to edit.
3. Select the tab by clicking on it.
4. Click on the **Edit** icon and enter a new name for the tab.
5. Click on the **OK** button to apply the change.

When you delete a tab, the fields that are on the tab will be taken off the screen. You will need to re-add or move them to a different tab if you still want those fields to appear on the screen. You cannot delete the last tab on the screen. To delete a tab, perform the following steps:

1. Browse to the **View Screens** page.
2. Click on the **Configure** link for the screen that has the tab you wish to edit.
3. Select the tab by clicking on it.
4. Click on the **Delete** icon. JIRA will ask you to confirm whether you want to delete the tab and list all the fields present.
5. Click on the **Delete** button to remove the tab from the screen.

Working with screen schemes

You have seen how we can create and manage screens and how to configure what fields to add to the screens. The next piece of the puzzle is letting JIRA know how to choose the screen that has to be displayed for each issue operation.

Screens are displayed during issue operations, and a screen scheme defines the mapping between screens and the operations. With a screen scheme, you can control the screen for displaying each of the issue operations, as follows:

- **Create Issue:** This screen is shown when you create a new issue
- **Edit Issue:** This screen is shown when you edit an existing issue
- **View Issue:** This screen is shown when you view an issue

Just like screens, whenever you create a new project in JIRA, a new screen scheme is created specifically for your project, and screens are automatically assigned to these issue operations.

The defaults created are usually good enough to get started with; however, there will be times when you would wish that certain fields should not be available for editing once the issue is created, such as **Issue Type**. You may want to have finer control over the type of issues raised for reporting and statistical measurement reasons, so it is not a good idea to let users freely change the issue type. Another example would be that certain fields are not required during creation because the required information may not be available at the time. Therefore, instead of confusing and/or overwhelming your users, leave those fields out during issue creation and only ask for them to be filled in at a later time when the information becomes available.

As you can see, by dividing the screen into multiple issue operations rather than having the one-screen-fits-all approach, JIRA provides you with a new level of flexibility to control and design your screens. As always, if there are no significant differences between the screens, for example, create and edit, it is recommended that you create a base screen and use the **Copy Screen** feature to reduce your workload.

Just like screens, you need to be a JIRA administrator to manage screen schemes. Perform the following steps to manage screen schemes:

1. Browse to the JIRA administration console.
2. Select the **Issues** tab and then the **Screen schemes** option to bring up the **View Screen Schemes** page:

View Screen Schemes

[+ Add Screen Scheme](#)

Screen Schemes allow you to choose what screens are shown for each issue operation. Screen Schemes are mapped to issue types using Issue Type Screen Schemes, which can be associated with one or more projects.

Note: a screen scheme can only be deleted if it is not used in a Issue Type Screen Scheme.

Name	Issue type screen schemes	Operations
DEMO: Scrum Bug Screen Scheme	• DEMO: Scrum Issue Type Screen Scheme	Configure · Edit · Copy
DEMO: Scrum Default Screen Scheme	• DEMO: Scrum Issue Type Screen Scheme	Configure · Edit · Copy
Default Screen Scheme Default Screen Scheme	• Default Issue Type Screen Scheme	Configure · Edit · Copy

From the **View Screen Schemes** page, you will be able to see a list of all the existing screen schemes, create and manage their configurations, and view their associations with issue type screen schemes (explained in the later section).

Adding a screen scheme

Usually, you will be using the JIRA created screen scheme for your project. However, there will be cases where you need more than one. For example, if you need to display different set of screens based on the various issue types you have in your project, you will need to create a new screen scheme for each issue type. Perform the following steps to create a new screen scheme:

1. Browse to the **View Screen Schemes** page.
2. Click on the **Add Screen Scheme** button.
3. Enter a meaningful name and description for the new screen scheme.
4. Select a default screen from the list of screens. This screen will be displayed when no specific issue operation is mapped.
5. Click on the **Add** button to create the screen scheme.

At this stage, the new screen scheme is not in use. This means that it is not associated with any issue type screen schemes yet (issue type screen schemes are covered in the later sections).

After a screen scheme is created, it will apply the selected default screen to all the issue operations. We will look at how to associate screens to issue operations in later sections.

Editing/deleting a screen scheme

You can update the details of the existing screen schemes, such as its name and description. In order for you to make changes to the default screen selection, you need to configure the screen scheme, which will be covered in later sections. Perform the following steps to edit an existing screen scheme:

1. Browse to the **View Screen Schemes** page.
2. Click on the **Edit** link for the screen scheme you wish to edit. This will take you to the **Edit Screen Scheme** page.
3. Update the name and description with new values.
4. Click on the **Update** button to apply the changes.

Inactive screen schemes can also be deleted. If the screen scheme is active (that is, associated with an issue type screen scheme), then the delete option will not be present. Perform the following steps to delete a screen scheme:

1. Browse to the **View Screen Schemes** page.
2. Click on the **Delete** link for the screen scheme you wish to delete. This will take you to the **Delete Screen Scheme** page.
3. Click on the **Delete** button to confirm that you wish to delete the screen scheme.

Copying a screen scheme

While screen schemes are not as complicated as screens, there will still be times when you would like to copy an existing screen scheme rather than creating one from scratch. You might wish to copy the scheme's screens/issue operations associations, which we will cover in the following section, or make a quick backup copy before making any changes to the scheme.

Perform the following steps to copy an existing screen scheme:

1. Browse to the **View Screen Schemes** page.
2. Click on the **Copy** link for the screen scheme you wish to copy. This will take you to the **Copy Screen Scheme** page.
3. Enter a new name and description for the screen scheme.
4. Click on the **Copy** button to copy the selected screen scheme.

Just like creating a new screen scheme, copied screen schemes are inactive by default.

Configuring a screen scheme

As mentioned earlier, when you create a new screen scheme, it will use the same screen selected as your default screen for all issue operations. Now, if you want to use the same screen to create, edit, and view, then you are all set; there is no need to perform any further configuration to your screen scheme. However, if you need to have different screens displayed for different issue operations, then you will need to establish this association.

When an issue operation does not have an association with a screen, the selected default screen will be applied. If the issue operation is later given in a screen association, then the specific association will take precedence over the general fallback default screen.

The associations between screens and issue operations are managed on a per-screen scheme level. Perform the following steps to configure a screen scheme:

1. Browse to the **View Screen Schemes** page.
2. Click on the **Configure** link for the screen scheme you wish to configure. This will take you to the **Configure Screen Scheme** page.

Associating screens to issue operations

Each issue operation can be associated with one or more issue operations. Perform the following steps to associate an issue operation with a screen:

1. Browse to the **Configure Screen Scheme** page for the screen scheme to be configured.
2. Click on the **Add an Issue Operation with a Screen** button.
3. Select an issue operation to be assigned to a screen.
4. Select the screen to be associated to the issue operation.
5. Click on the **Add** button to create the association.

Configure Screen Scheme — HD: Task Management Screen Scheme

+ Associate an Issue Operation with a Screen

SHARED BY 1 PROJECT

Please use the table and the form below to select which screen will be displayed for each issue operation. The *Default* entry is used to indicate which screen should be used for operations that do not have a specific mapping in this scheme.

To activate this screen scheme, map it to one or more issue types using an [Issue Type Screen Scheme](#) and then associate the Issue Type Screen Scheme with one or more projects.

Note: a screen scheme can only be deleted if it is not a default scheme and is not associated with any projects.

- [View all screen schemes](#)

Issue Operation	Screen	Operations
<i>Default</i> Used for all unmapped operations.	HD: Task Management View Issue Screen	Edit
Create Issue	HD: Task Management Create Issue Screen	Edit · Delete
Edit Issue	HD: Task Management Edit Issue Screen	Edit · Delete

As shown in the preceding screenshot, the **Create Issue** and **Edit Issue** operations are associated with **HD: Task Management Create Issue Screen** and **HD: Task Management Edit Issue Screen**, respectively. Since we do not have a screen associated with the **View Issue** operation, the default association of **HD: Task Management View Issue Screen** will be used.

Editing/deleting an association

After you create an association for an issue operation, JIRA prevents you from creating another association for the same issue operation by removing it from the list of available options. In order to change the association to a different screen, you need to edit the existing association, as follows:

1. Browse to the **Configure Screen Scheme** page for the screen scheme to be configured.
2. Click on the **Edit** link for the association you wish to edit. This will take you to the **Edit Screen Scheme Item** page.
3. Select a new screen to associate with the issue operation.
4. Click on the **Update** button to apply the change.

If you decide that one or more existing associations are no longer needed, then you can delete them from the screen scheme by performing the following steps:

1. Browse to the **Configure Screen Scheme** page for the screen scheme to be configured.
2. Click on the **Delete** link for the association you wish to delete.

Please note that unlike other similar operations, deleting an issue operation association does not prompt you with a confirmation page. As soon as you click on the **Delete** link, your association will be deleted immediately.

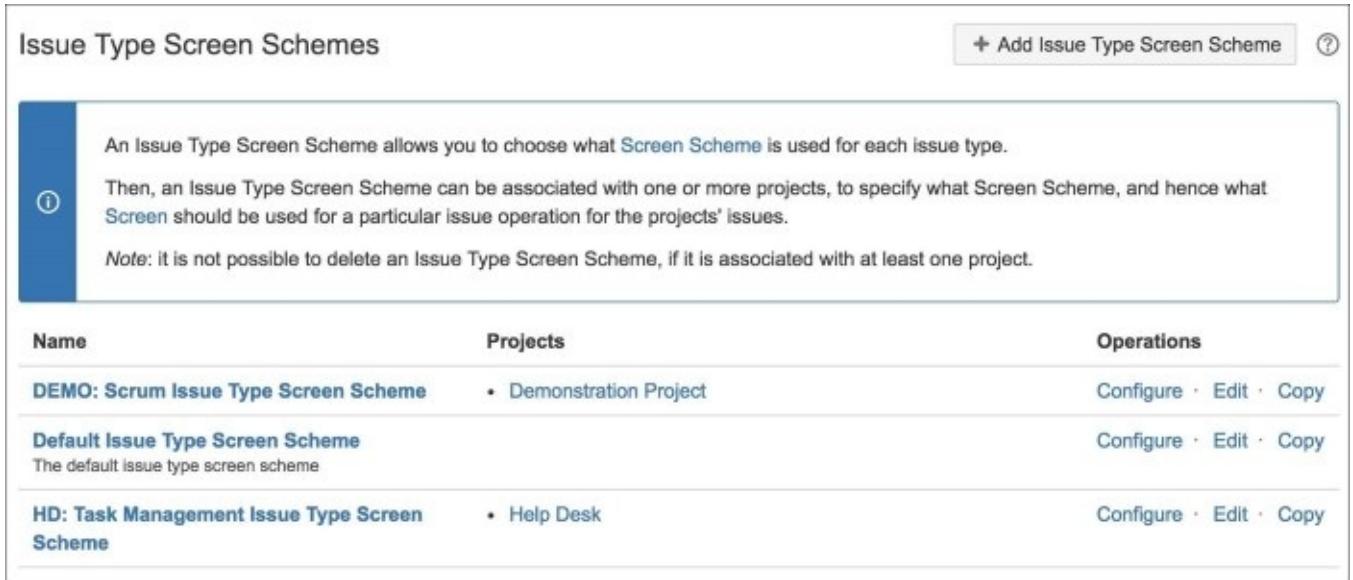

Issue type screen scheme

Screen schemes group screens together and create associations with issue operations. The next piece of the puzzle is to tell JIRA to use our screen schemes when creating, viewing, and editing specific types of issues.

We do not directly associate screen schemes to JIRA. The reason for this is that JIRA has the flexibility to allow you to define this on a per-issue type level. What this means is, instead of forcing all the issue types in a given project to use the same screen scheme, you can actually use different screen schemes for different issue types. This extremely flexible and powerful feature is provided through the issue type screen scheme.

Just like screens and screen schemes, you need to be a JIRA administrator to create and manage issue type screen schemes. Perform the following steps to manage issue type screen schemes:

1. Browse to the JIRA administration console.
2. Select the **Issues** tab and then the **Issue type screen schemes** option to bring up the **Issue Type Screen Schemes** page:

Name	Projects	Operations
DEMO: Scrum Issue Type Screen Scheme <small>The default issue type screen scheme</small>	• Demonstration Project	Configure · Edit · Copy
Default Issue Type Screen Scheme		Configure · Edit · Copy
HD: Task Management Issue Type Screen Scheme	• Help Desk	Configure · Edit · Copy

Adding an issue type screen scheme

Just like screen scheme, JIRA will automatically create an issue type screen scheme when you create your project. Since one project can only have one issue type screen scheme associated, usually you will not need to create new ones yourself. However, there might be a time when you want to create a new scheme, such as experimenting with some new configurations while still wanting to keep the existing one untouched in case of a roll back.

Perform the following steps to create a new issue type screen scheme:

1. Browse to the **Issue Type Screen Schemes** page.
2. Click on the **Add Issue Type Screen Scheme** button.
3. Enter a name and description for the new issue type screen scheme.
4. Select a default screen scheme from the list of screen schemes.
5. Click on the **Add** button to create the issue type screen scheme.

That's right, you guessed it! The new issue type screen scheme is not yet in use. It will only become active once it is applied to one or more projects, which we will look at shortly.

Editing/deleting an issue type screen scheme

You can make updates to an existing issue type screen scheme's name and descriptions. To change its screen scheme/issue type association details, you need to configure the issue type screen scheme, which will be covered in later sections. Perform the following steps to update an issue type screen scheme:

1. Browse to the **Issue Type Screen Schemes** page.
2. Click on the **Edit** link for the issue type screen scheme you wish to edit. This will take you to the **Edit Issue Type Screen Scheme** page.
3. Update the name and description with new values.
4. Click on the **Update** button to apply the changes.

Just like all other schemes in JIRA, you cannot delete issue type screen schemes that are in use. You will have to make sure that no project uses it before JIRA allows you to delete the scheme. To delete issue type screen schemes perform the following steps:

1. Browse to the **Issue Type Screen Schemes** page.
2. Click on the **Delete** link for the issue type screen scheme you wish to delete. This will take you to the **Delete Issue Type Screen Scheme** page.
3. Click on the **Delete** button to remove the issue type screen scheme.

Copying an issue type screen scheme

Issue type screen scheme cloning is also available in JIRA. You can easily make copies of the existing issue type screen schemes. One very useful application of this feature is that it enables you to make backup copies before experimenting with new configurations. Note that copying the issue type screen scheme does not back up the screen schemes and screens that it contains.

Perform the following steps to copy an existing issue type screen scheme:

1. Browse to the **Issue Type Screen Schemes** page.
2. Click on the **Copy** link for the issue type screen scheme you wish to copy. This will take you to the **Copy Issue Type Screen Scheme** page.
3. Enter a new name and description for the issue type screen scheme.
4. Click on the **Copy** button to copy the selected scheme.

The newly created issue type screen schemes are inactive by default, while cloned schemes are not used by any projects.

Configuring an issue type screen scheme

By creating new issue type screen schemes, you can establish new associations between screen schemes and issue types. These associations are what tie the projects and issue types to the individual screens.

Each issue type screen scheme needs to be configured separately, and the associations created are specific to the configured scheme:

1. Browse to the **Issue Type Screen Schemes** page.
2. Click on the **Configure** link for the issue type screen scheme you wish to configure. This will take you to the **Configure Issue Type Screen Scheme** page.

Associating issue types to screen schemes

JIRA determines which screen scheme to use for an issue type by establishing an association between screen schemes and issue types. Each issue type can have only one screen scheme associated with it. However, each screen scheme can be associated with more than one issue type.

Perform the following steps to add a new association:

1. Browse to the **Configure Issue Type Screen Scheme** page for the issue type screen scheme you wish to configure.
2. Click on the **Associate an Issue Type with a Screen Scheme** button.
3. Select the issue type to add an association for.
4. Select the screen scheme to be associated with the issue type.
5. Click on the **Add** button to create the association:

The screenshot shows the 'Configure Issue Type Screen Scheme' page for the 'DEMO: Scrum Issue Type Screen Scheme'. At the top, there's a header with the screen scheme name and a 'Associate an Issue Type with a Screen Scheme' button. Below the header, there's a note about the scheme being shared by one project. A blue sidebar contains a general note about the scheme being used by multiple projects and a specific note about the 'Default' entry. There's also a link to view all issue type screen schemes. The main table lists four issue types: 'Default' (unmapped), 'Story' (selected), 'Task' (selected), and 'Bug' (unselected). Each row shows the issue type, its associated screen scheme, and 'Edit' and 'Delete' operations.

Issue Type	Screen Scheme	Operations
Default Used for all unmapped issue types.	DEMO: Scrum Default Screen Scheme	Edit
<input checked="" type="checkbox"/> Story	DEMO: Scrum Story Screen Scheme	Edit · Delete
<input checked="" type="checkbox"/> Task	DEMO: Scrum Task Screen Scheme	Edit · Delete
<input type="checkbox"/> Bug	DEMO: Scrum Bug Screen Scheme	Edit · Delete

As shown in the preceding screenshot, the **Story**, **Task**, and **Bug** issue types are explicitly associated with DEMO: Scrum Story Screen Scheme, Demo: Scrum Task Screen Scheme, and DEMO: Scrum Bug Screen Scheme, respectively. All other issues types, such as **Improvement**, will be associated with the default DEMO: Scrum Default Screen Scheme.

Editing/deleting an association

You can update the existing associations, such as the **Default** association, which is created automatically when you create a new issue type screen scheme:

1. Browse to the **Configure Issue Type Screen Scheme** page for the issue type screen scheme to be configured.
2. Click on the **Edit** link for the association you wish to edit. This will take you to the **Edit Issue Type Screen Scheme** page.
3. Select a new screen scheme to associate with the issue type.
4. Click on the **Update** button to apply the change.

You can also delete the existing associations for issue types if you no longer need them to be explicitly set. However, you cannot delete the **Default** association, since it is used as a catch for all the issue types that do not have an association defined. This is important because while you may have created associations for all the issue types right now, you might add new issue types down the track and forget to create associations for them. To delete an association:

1. Browse to the **Configure Issue Type Screen Scheme** page for the issue type screen scheme to be configured.
2. Click on the **Delete** link for the association you wish to delete.

Just like associations in screen schemes, you will not be taken to a confirmation dialog, and the association will be deleted immediately.

Associating an issue type screen scheme with a project

Perform the following steps in order to activate your new issue type screen scheme, which will display your new screens for the different issue operations:

1. Browse to the target project's administration page.
2. Click on the **Screens** option from the left panel.
3. Select the **Use a different scheme** option from the **Actions** menu:

The screenshot shows the JIRA administration interface for a project named "DEMO: Scrum Issue Type Screen Scheme". The "Actions" menu is open, with the "Use a different scheme" option highlighted. Below, a table lists the mapping between issue types and screen schemes. The table has three columns: "This issue type...", "...uses this screen scheme", and "screen and issue operation mapping". The "Issue Type" column contains "Bug". The "Screen" column contains "DEMO: Scrum Bug Screen" for all three operations: "Create Issue", "Edit Issue", and "View Issue".

This issue type...	...uses this screen scheme	screen and issue operation mapping
Bug	DEMO: Scrum Bug Screen	Create Issue
	DEMO: Scrum Bug Screen	Edit Issue
	DEMO: Scrum Bug Screen	View Issue

4. Select the issue type screen scheme from the **Scheme** select list.
5. Click on the **Associate** button.

Once you associate the issue type screen scheme with the project, JIRA will show you the details of the mapping, as shown in the preceding screenshot.

The HR project

Armed with the new knowledge that you gathered in this chapter, together with fields from the previous chapter, it is time for you to further customize your JIRA to provide a better user experience through the presentation.

What we will do this time is create new screens and apply them to our **Help Desk** project. We want to separate the generic fields from our specialized custom fields designed for escalation. We also want to, at this time, apply the changes to the issues of the **Incident** type only and not affect the other issue types. As with any changes to be done on a production system, it is critical that you have a backup of your current data before applying changes.

Setting up screens

In [Chapter 5](#), *Field Management*, you created a few custom fields specifically designed for our HR team. The problem we had is all the new fields are showing up for both **New Employee** and **Termination** issue types, regardless of whether they are applicable, and this is because both issue types use the same set of screens.

So to address this, we will create two new sets of screens, one for **New Employee** and one for **Termination**. The default one can be left for other issue types we have in the project, such as **Task**.

The easiest way to do this will be to clone the existing screens, so we do not have to manually add all the fields, and avoid forgetting to add a field by accident. To create screens for each issue type, perform the following steps:

1. Browse to the **View Screens** page and click on the **Copy** link for **HR: Task Management Create Issue Screen**.
2. Name the new screen **HR: Create/View New Employee Screen**.
3. Click on the **Copy** button to create the screen.

Now that we have our new screen, it is time to configure its fields. Since this screen is for creating **New Employee** issues, we do not need the **Last Day** field:

1. Click on the **Configure** link of our new **HR: Create/View New Employee Screen**.
2. Remove the **Last Day** field by hovering over it and clicking its **Remove** button.

Just to spice things up a bit, we can also create a new tab called **People** and move all people-related fields, such as the **Assignee**, **Reporter**, and **Direct Manager** fields, onto that tab.

We created and configured our create screen. Our new edit screen is going to look very similar to this with just a few modifications. We want to take the **Issue Type** field off, since we do not want users to change the issue type after it is created:

1. Click on the **Copy** link for **HR: Create/View New Employee Screen**.
2. Name the new screen **HR: Edit New Employee Screen**.
3. Click on the **Copy** button to create the new screen.
4. Remove the **Issue Type** field.

Repeat the steps to create a new set of screens for the **Termination** issue type. This time, instead of removing the **Last Day** field, and remove the **Direct Manager** field from both screens.

Setting up screen schemes

With the screens created and configured, we now need to link them up with issue operations so that JIRA will know on which action the new screens will be displayed, using the following steps:

1. Browse to the **View Screen Schemes** page and click on **Add Screen Scheme**.
2. Name the new screen scheme as **HR: New Employee Screen Scheme**.
3. Select **HR: Create/View New Employee Screen** as the default screen.
4. Click on the **Add** button to create the screen scheme.

With our screen scheme in place, it is time to link up our screens with their respective issue operations:

1. Click on the **Associate an Issue Operation** with a **Screen** button.
2. Select **HR: Edit New Employee Screen** for the **Edit Issue** operation.

Since we assigned **HR: Create/View New Employee Screen** to **Default**, this screen will be applied to the unmapped operations, **Create Issue** and **View Issue**. There are no differences if you choose to explicitly set the mappings for the preceding two operations.

We have created the screen scheme for **New Employee** issue type, now repeat the same steps for **Termination** issue type.

Setting up issue type screen schemes

Now, you need to tell JIRA which issue type to apply the screen scheme to that you just created. Since JIRA has already created an issue type screen scheme for our project, we just need to configure it to use our new screen schemes for the appropriate issue types:

1. Browse to the **Issue Type Screen Schemes** page and click on the **Configure** link for **HR: Task Management Issue Type Screen Scheme**.
2. Click on the **Associate an Issue Type with a Screen Scheme** button.
3. Select **New Employee** for **Issue Type**.
4. Select **HR: New Employee Screen Scheme** for the screen scheme to be associated.
5. Click on the **Add** button to create the association.

This will ensure that issues of type **New Employee** will have your new screens applied, while issues of other types will not be affected. Now repeat the steps to associate the **Termination** issue type with its screen scheme.

Putting it together

Since we are re-using the existing issue type screen scheme by associating various issue types to our new screen schemes, we do not need to make any additional changes. However, if you created a new issue type screen scheme instead, you will need to associate it with the HR project.

You can now take a look at your hard work and see your custom screens, fields, and tabs all working nicely together to present you with a custom form for collecting user data. Let's go ahead and create a new incident and see what your newly customized **Create Issue** screen will look like, as shown in the following screenshot:

The screenshot shows the 'Create Issue' interface. At the top, there are dropdown menus for 'Project' (set to 'Human Resource (HR)') and 'Issue Type' (set to 'New Employee'). A message below the dropdowns states: 'Some issue types are unavailable due to incompatible field configuration and/or workflow associations.' Below these, there are two tabs: 'Field Tab' (selected) and 'People'. Under the 'Field Tab' tab, there are fields for 'Reporter' (set to 'patrick@appfusions.com'), 'Assignee' (set to 'Automatic'), and 'Direct Manager' (empty). Below each assignee field is a placeholder text: 'Start typing to get a list of possible matches.' At the bottom right of the screen are buttons for 'Create another', 'Create' (which is highlighted in blue), and 'Cancel'.

As you can see, the **Last Day** field is no longer showing on the screen when you create a **New Employee** issue, and our people-related fields are now showing on the new **People** tab. If you create a new **Termination** issue, the **Direct Manager** field will not show.

Summary

In this chapter, we looked at how JIRA structures its presentation with screens. We looked at how screens are used in JIRA via screen schemes, which map screens to issue operations. We also looked at how issue type screen schemes are then used to map screen schemes to issue types. Therefore, for any given project, each issue type can have its own set of screens for create, edit, and view. We also discussed how screens can be broken down into tabs to provide a more logical grouping of fields, especially when your screen starts to have a lot of fields on it.

Together with custom fields that we saw in the previous chapter, we can now create effective screen designs to streamline our data collection. In the next chapter, we will delve into one of the most powerful features in JIRA, **workflows**.

Chapter 7. Workflow and Business Process

In the previous chapters, you learned some of the basics of JIRA and how to customize its data capture and presentation with custom fields and screens. In this chapter, we will dive in and take a look at workflows, one of the core and most powerful features in JIRA.

A workflow controls how issues in JIRA move from one status to another, as they are being worked on, often passing from one assignee to another. Unlike many other systems, JIRA allows you to create your own workflows to resemble your processes.

By the end of this chapter, you will have learned the following:

- What a workflow is and what it consists of
- About the relationship between workflows and screens
- What are statuses, transitions, conditions, validators, and post functions
- How to create your own workflow with the workflow designer
- How to associate a workflow with projects

Mapping business processes

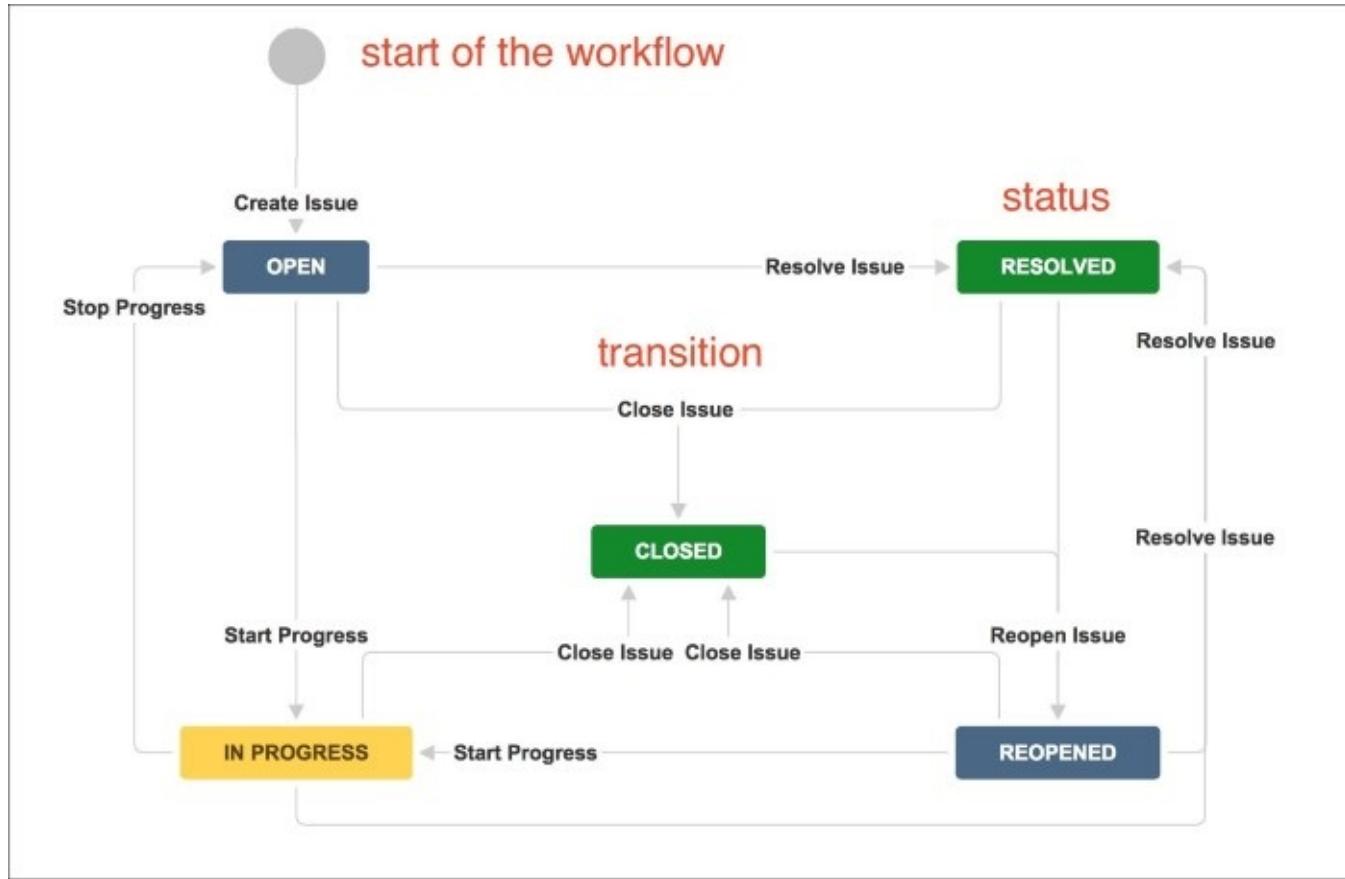

It is often said that a good software system is one that adapts to your business and not one that requires your business to adapt to the software. JIRA is an excellent example of the former. The power of JIRA is that you can easily configure it to model your existing business processes through the use of workflows.

A business process flow can often be represented as a flow chart. For example, a typical document approval flow may include tasks such as document preparation, document review, and document submission, where the user needs to follow these tasks in a sequential order. You can easily implement this as a JIRA workflow. Each task will be represented as a workflow status with transitions guiding you on how you can move from one status to the next. In fact, when working with workflows, it is often a good approach to first draft out the logical flow of the process as a flow chart and then implement this as a workflow. As we will see, JIRA provides many tools to help you visualize your workflows.

Now that we have briefly seen how you can map a normal business process to a JIRA workflow, it is time to take a closer look at the components of a workflow and how you can create your own workflows.

Understanding workflows

A workflow is what JIRA uses to model business processes. It is a flow of statuses (steps) that issues go through one by one with paths between them (transitions). All issues in JIRA have a workflow applied based on their issue type and project. Issues move through workflows from one status (for example, **OPEN**) to another (for example, **CLOSED**). JIRA lets you visualize and design workflows as a diagram, as shown in the following diagram:

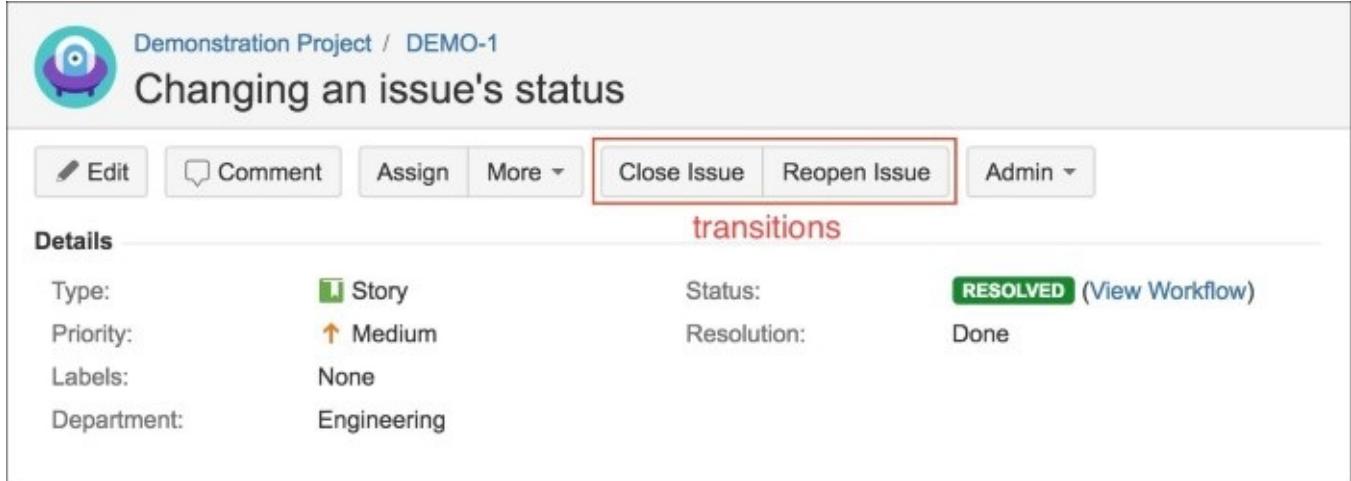

The preceding diagram shows a simple workflow in JIRA. The rectangles represent the statuses, and the arrow lines represent transitions that link statuses together. As you can see, this looks a lot like a normal flow chart depicting the flow of a process.

Also notice that statuses have different colors. The color of a status is determined by the **category** it belongs to. There are three categories, To Do (blue), In Progress (yellow), and Done (green). Categories help you to easily identify where along the workflow an issue is at, by using color as an indicator.

Issues in JIRA, starting from when they are created, go through a series of steps identified as **issue statuses**, such as **In Progress** and **Closed**. These movements are often triggered by user interactions. For example, when a user clicks on the **Start Progress** link, the issue is

transitioned to the **In Progress** status, as shown in the following screenshot:

The screenshot shows a JIRA issue details page for a Story titled "Changing an issue's status". The top navigation bar includes "Edit", "Comment", "Assign", "More", "Close Issue", "Reopen Issue", and "Admin". The "Close Issue" and "Reopen Issue" buttons are highlighted with a red border. Below the navigation is a section titled "transitions" which lists the current status as "RESOLVED (View Workflow)" with a resolution of "Done". The issue details table includes fields for Type (Story), Priority (Medium), Labels (None), and Department (Engineering).

There is a definitive start of a workflow, which is when the issue is first created, but the end of a workflow can sometimes be ambiguous. For example, in the default workflow, issues can go from **Open** to **Closed** to **Reopened** and back to **Closed**. By convention, when people talk about the end of a workflow, they are usually referring to a status named **Closed** or the status where issues are given a **resolution**. Once a resolution is given, the issue comes to a logical end. Several built-in features of JIRA follow this convention, for example, issues with resolutions set will not be displayed on the **Assigned to Me** list on the home page.

Note

When work for an issue is completed, it should be given a resolution.

Managing workflows

Workflows are controlled and managed centrally from the JIRA administration console, so you need to be an administrator to create and configure workflows. To manage workflows, perform the following steps:

1. Log in to JIRA as a JIRA administrator.
2. Browse to the JIRA administration console.
3. Select the **Issues** tab and then the **Workflows** option. This will bring up the **View Workflows** page:

The screenshot shows the 'Workflows' page in the JIRA administration console. At the top right are buttons for '+ Add Workflow', 'Import', and a help icon. Below is a message: 'To delete a workflow, you must first unassign it from all workflow schemes and draft workflow schemes.' The page is divided into sections: 'Active' and 'Inactive'. The 'Active' section is expanded, showing three workflows:

Name	Last modified	Assigned Schemes	Steps	Operations
HD: Task Management Workflow Task Management workflow	23/Aug/16 patrick@appfusions.com	• HD: Task Management Workflow Scheme	2	View · Edit · Copy
HR: Task Management Workflow Task Management workflow	24/Aug/16 patrick@appfusions.com	• HR: Task Management Workflow Scheme	2	View · Edit · Copy
Software Simplified Workflow for Project DEMO Generated by JIRA Software version 7.1.23- DAILY20160627065553. This workflow is managed internally by JIRA Software. Do not manually modify this workflow.	28/Aug/16 patrick@appfusions.com	• DEMO: Software Simplified Workflow Scheme	3	View · Edit · Copy

The 'Inactive' section is collapsed. It contains two entries:

Name	Last modified	Assigned Schemes	Steps	Operations
jira (Read-only System Workflow) DEFAULT The default JIRA workflow.			5	View · Copy
classic default workflow The classic JIRA default workflow		• classic	5	Edit · Copy

From the **View Workflows** page, you will be able to see a list of all the available workflows. You can also create new workflows and manage existing ones. The page is divided into two sections, **Active** and **Inactive**. Active workflows are being used by projects, and inactive ones are not. By default, the **Inactive** section is collapsed, so the page will only display active workflows. The preceding screenshot shows the **Inactive** section being expanded.

JIRA comes with a default read-only workflow called **jira**. This workflow is applied to projects that do not have any specific workflow applied. For this reason, you cannot edit or delete this workflow. With JIRA 7, this is mostly used to remain backward compatible with

existing projects. New projects will have their own workflows created based on the template selected. These project-specific workflows will have their names start with the project key, followed by the project's template, such as HD: Task Management Workflow.

Issue statuses

In a JIRA workflow, an **issue status** represents a state in the workflow for an issue. It describes the current status of the issue. If we compare it to a flow chart, the statuses will be the rectangles and in the diagram they indicate the current status of the issue along the process. Just as a task can only be in one stage of a business process, an issue can be in only one status at any given time, for example, an issue cannot be both open and closed at the same time.

There is also a term called **step**, which is the workflow terminology for statuses. Since JIRA has simplified its workflow administration, step and status can be used interchangeably. For consistency, we will be using the term status in this book, unless a separation needs to be made in special cases.

Transitions

Statuses represent stages in a workflow; the path that takes an issue from one status to the next is known as a **transition**. A transition links two statuses together. A transition cannot exist on its own, meaning it must have a start and finish status and can only have one of each. This means that a transition cannot conditionally split off to different destination statuses.

Transitions are also one way only. This means that if a transition takes an issue from status A to status B, you must create a new transition if you want to go back from status B to status A.

Transitions have several components. They are as follows:

- **Conditions:** Criteria must be met before the transition is available (visible) for users to execute. It is usually used to control permissions around how users can execute the transition.
- **Validators:** These are the verifications that must pass before the transition can be executed. They are usually used together with **Transition Screens**.
- **Post Functions:** These are additional functions to be performed as part of the transition process.
- **Transition Screen:** This is an optional screen to be displayed when a user is executing the transition. It is usually used to capture additional information as a part of the transition.
- **Triggers:** If you have integrated JIRA with other development tools such as Stash or GitHub, triggers can automatically execute the transition when an event happens, such as the creation of a new branch or when someone makes a code commit.

Each of the first three components defines the behavior of the transitions, allowing you to perform pre-and post-validations, as well as post-execution processing on the transition execution. We will discuss these components in depth in the following sections.

Triggers

As described earlier, JIRA needs to be integrated with one of the following systems before you can start using triggers:

- Atlassian Stash
- Atlassian FishEye/Crucible
- Atlassian Bitbucket
- GitHub

Triggers will listen for changes from the integrated development tools, such as code commits, and when these happen, the trigger will automatically execute the workflow transition. Note that all permissions are ignored when this happens.

Conditions

Sometimes, you might want to have control over who can execute a transition or when a transition can be executed. For example, a transition to authorize an issue should be restricted to users in the managers group so normal employees will not be able to authorize their own requests. This is where conditions come in.

Conditions are criteria that must be fulfilled before the user is allowed to execute the transition. If the conditions on transitions are not met, the transition will not be available to the user when viewing the issue. The following table shows a list of conditions that are shipped with JIRA:

Condition	Description
Code Committed Condition	This allows the transition to execute only if code has/has not (depending on configuration) been committed against this issue.
Hide transition from user	This will hide the transition from all users, and it can only be triggered from post functions. This is useful in situations where the transition will be triggered as part of an automated process rather than manually by a user.
No Open Reviews Condition	This allows a transition to execute only if there are no related open crucible reviews.
Only Assignee Condition	This only allows the issue's current assignee to execute the transition.
Only Reporter Condition	This only allows the issue's reporter to execute the transition.
Permission Condition	This only allows users with the given permission to execute the transition.
Sub-Task Blocking	This blocks the parent issue transition depending on all its subtasks' statuses.

Condition	
Unreviewed Code Condition	This allows transition to execute only if there are no unreviewed change sets related to this issue.
User Is In Group	This only allows users in a given group to execute the transition.
User Is In Group Custom Field	This only allows users in a given group custom field to execute a transition.
User Is In Project Role	This only allows users in a given project role to execute a transition.

Validators

Validators are similar to conditions as they validate certain criteria before allowing the transition to complete. The most common use case for validators is to validate the user input during transition. For example, you can validate if the user has entered data for all fields presented on the workflow screen.

The following table shows a list of validators that come shipped with JIRA:

Validator	Description
Permission Validator	This validates that the user has the selected permission. This is useful when checking whether the person who has executed the transition has the required permissions.
User Permission Validator	This validates that the user has the selected permission where the <code>osworkflow</code> variable holding the username is configurable. This is obsolete.

Post functions

As the name suggests, post functions are functions that occur after (post) a transition has been executed. This allows you to perform additional processes once you have executed a transition. JIRA heavily uses post functions internally to perform a lot of its functions. For example, when you transition an issue, JIRA uses post functions to update its search indexes so your search results will reflect the change in issue status.

If a transition has failed to execute (for example, failing validation from validators), post functions attached to the transition will not be triggered. The following table shows a list of post functions that come shipped with JIRA:

Post function	Description
Assign to Current User	This assigns the issue to the current user if the current user has the assignable user permission.
Assign to Lead Developer	This assigns the issue to the project/component lead developer.
Assign to Reporter	This assigns the issue to the reporter.
Create Perforce Job Function	This creates a perforce job (if required) after completing the workflow transition.
Notify HipChat	This sends a notification to one or more HipChat rooms.
Trigger a Webhook	If this post function is executed, JIRA will post the issue content in JSON format to the URL specified.
Update Issue Field	This updates a simple issue field to a given value.

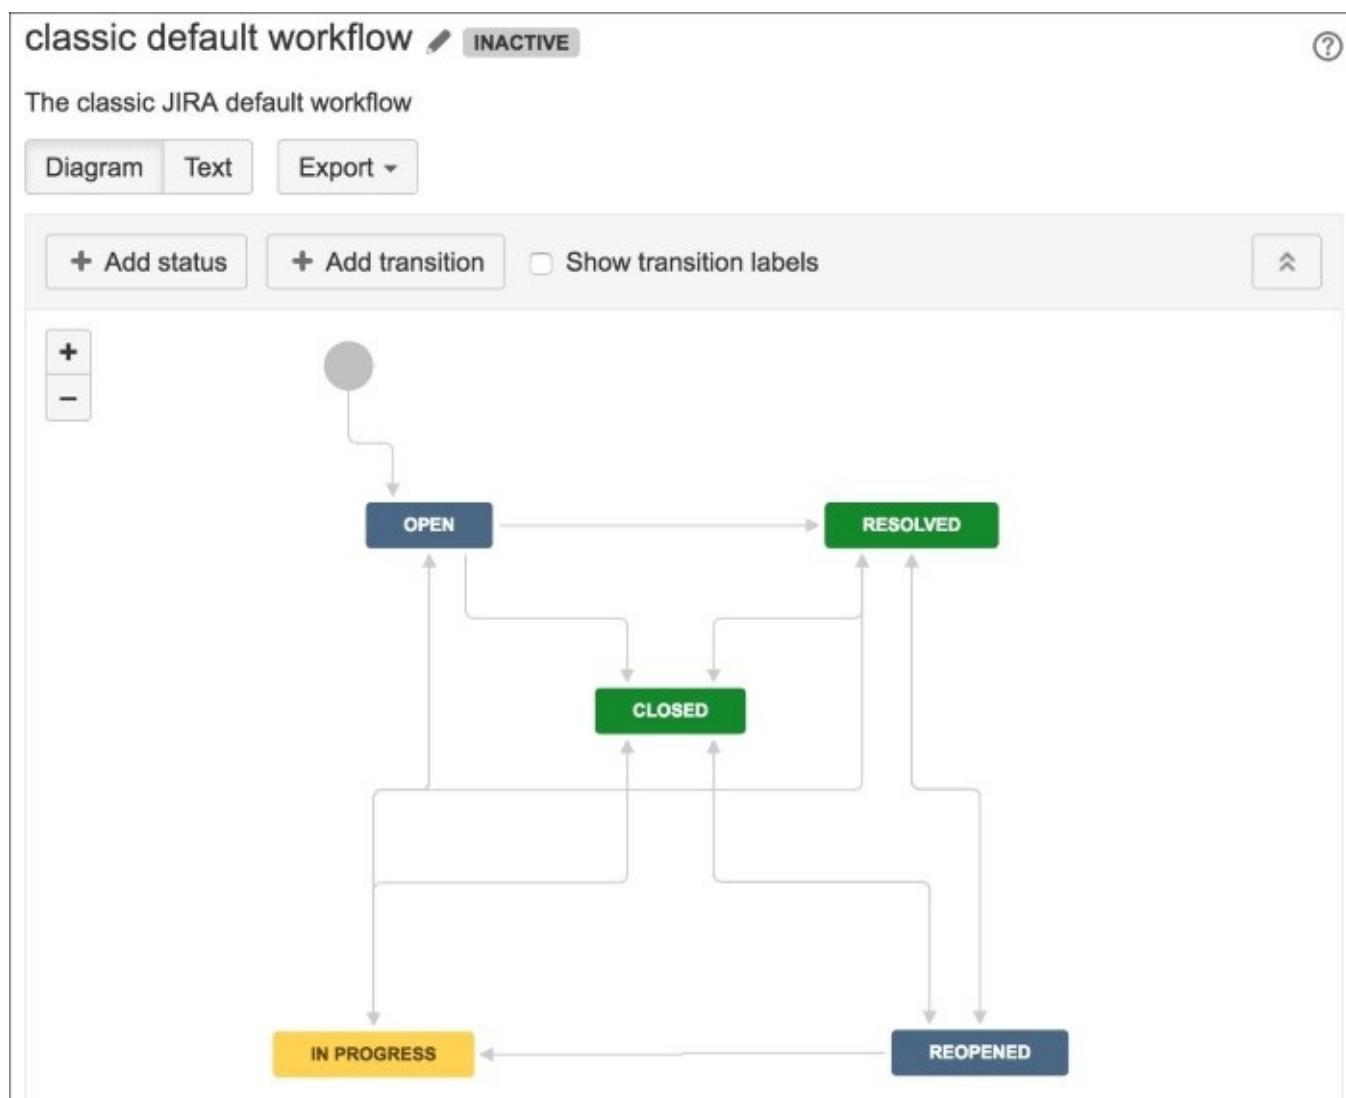

Using the workflow designer

JIRA comes with a simple to use, drag and drop tool called the **workflow designer**. This helps you create and configure workflows. If you are familiar with diagramming tools such as Microsoft Visio, you will feel right at home. There is also another older option, called the **Text mode**, available. However, since the designer is easier and has more features, we will focus on using the designer in this book.

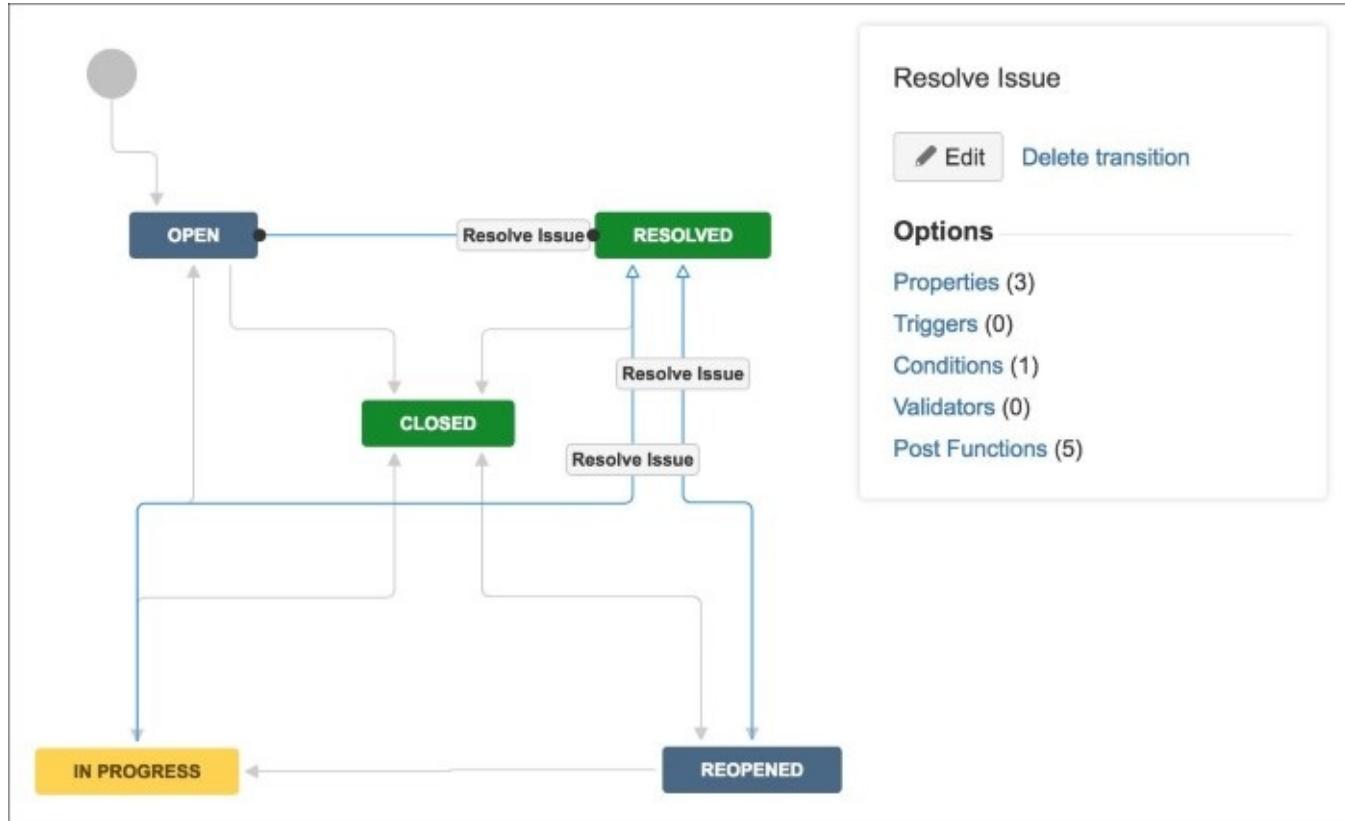

Tip

As your workflow becomes more complicated, the **Text** mode can be a better option to manage statuses and transitions in the workflow.

The workflow designer is shown in the following screenshot. You have the workflow layout in the main panel and a few controls on top, namely the **Add status** and **Add transition** buttons. Note that the **Diagram** option is selected. If you click on the **Text** option, JIRA will change to the old authoring tool:

From the workflow designer, you can drag and rearrange the statuses and transitions. Clicking on each will open up its property window, as shown in the following screenshot, where the **Resolved Issue** transition is selected. From here, we can view and update its properties, such as conditions and validators:

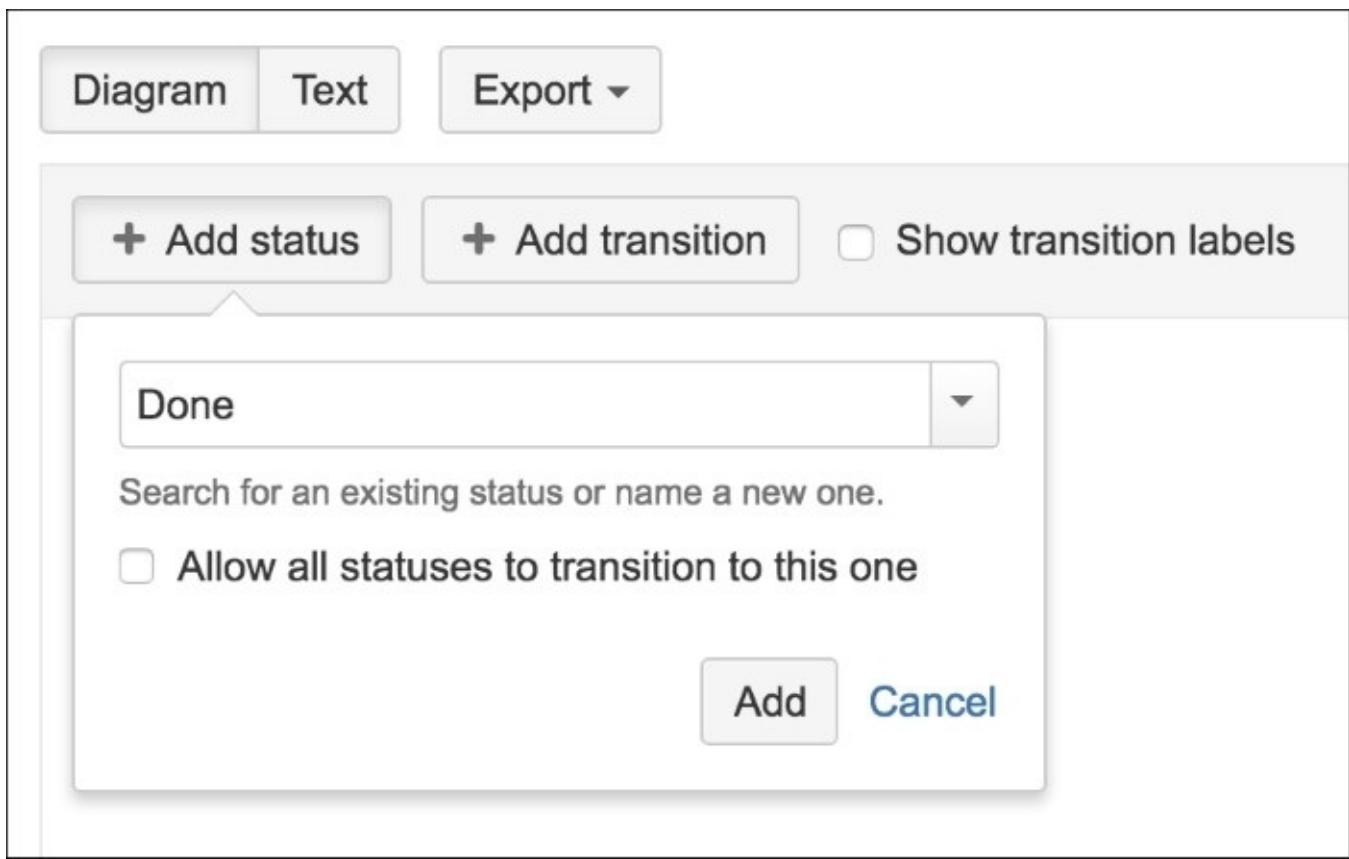

Authoring a workflow

So, let's take a look at how to create and set up a new workflow in JIRA. To create a new workflow, all you need is a name and description:

1. Browse to the **View Workflows** page.
2. Click on the **Add Workflow** button.
3. Enter a name and description for the new workflow in the **Add Workflow** dialog.
4. Click on the **Add** button to create the workflow.

The newly created workflow will only contain the default create and open status, so you will need to configure it by adding new statuses and transitions to make it useful. Let's start with adding new statuses to the workflow using the following steps:

1. Click on the **Add status** button.
2. Select an existing status from the drop-down list. If the status you need does not exist, you can create a new status by entering its name and pressing the **Enter** key on your keyboard.
3. Check the **Allow all statuses to transition to this one** option if you want users to be able to move the issue into this status regardless of its current status. This will create a **global transition**, which is a convenient option, so you do not have to manually create multiple transitions for the status.
4. Click on the **Add** button to add the status to your workflow. You can repeat these steps to add as many statuses as you want to your workflow:

Tip

Try to reuse existing statuses if possible so that you do not end up with many similar statuses to manage.

Now that the statuses are added to the workflow, they need to be linked with transitions so that issues can move from one status to the next. There are two ways to create a transition:

- Click on the **Add transition** button
- Select the originating status and then click and drag the arrow to the destination status

Both options will bring up the **Add Transition** dialog, as shown in the following screenshot:

Add Transition

New Transition Reuse a transition

From status *	Open
To status *	Resolved
Name *	Resolve Issue
Description	
Screen	Resolve Issue Screen

Add **Cancel**

From the preceding screenshot, you can choose to either create a new transition with the **New Transition** tab or use an existing transition with the **Reuse a transition** tab.

When creating a new transition, you will need to configure the following:

- **From status:** This is the originating status. The transition will be available when the issue is in the selected status.
- **To status:** This is the destination status. Once the transition is executed, the issue will be put into the selected status.
- **Name:** This is the name of the transition. This is the text that will be displayed to users. It is usually a good idea to name your transitions starting with a verb, such as `Close Issue`.
- **Description:** This is an optional text description showing the purpose of this transition. This will not be displayed to users.
- **Screen:** This is an optional intermediate screen to be displayed when users execute the transition. For example, you display a screen to capture additional data as part of the transition. If you do not select a screen, the transition will be executed immediately. The following screenshot shows a workflow screen:

Reopen Issue

i Reopening an issue indicates that it has not been completed, and should be looked at again.

Resolved

Transition to reuse *

Resolve Issue

Add

Cancel

Note

Note that JIRA will only list valid transitions based on the **To status** selection.

You might be wondering when you should create a new transition and when you should reuse an existing transition. The big difference between the two is that when you reuse a transition, all instances of the reused transition, also known as **common transition**, will share the same set of configurations, such as conditions and validators. Also, any changes made to the transition will be applied to all instances. A good use case for this is when you need to have multiple transitions with the same name and setup, such as `Close Issue`; instead of creating separate transitions each time, you can create one transition and reuse it whenever you need a transition to close an issue. Later on, if you need to add a new validator to the transition to validate additional user input, you will only need to make the change once, rather than multiple times for each `Close Issue` transition.

Another good practice to keep in mind is to not have a *dead end* state in your workflow, for example, allowing closed issues to be reopened. This will prevent users from accidentally closing an issue and not being able to correct the mistake.

One thing people often overlook is, you can change the status an issue is transitioned to when it is first created. By default, an issue is placed in the Open status as soon as it is created. While this makes sense for most cases, you can actually change that. For example, you might want all your issues to be in a Waiting status and transition to Open only after someone has

reviewed it. You can also make changes to the default **Create Issue** transition. By doing so, you can influence the issue creation process. For example, you can add a validator to it to add additional checking before an issue is allowed to be created, or add a post function to perform additional tasks as soon as an issue is created.

Now that we have seen how to add new statuses and transitions to a workflow, let's look at adding triggers, conditions, validators, and post functions to a transition.

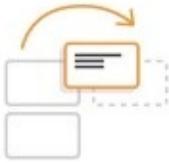

Adding a trigger to transitions

You can only add triggers to transitions if JIRA is integrated with at least one of the supported development tools. To add triggers, perform the following steps:

1. Select the transition you want to add triggers to.
2. Click on the **Triggers** link.
3. Click on the **Add trigger** button. If you do not have any integrated development tools, this button will be disabled:

Screen: Resolve Issue Screen

Triggers 0 Conditions 1 Validators 0 Post Functions 5

A trigger is an event that initiates an automatic transition for a JIRA issue. Examples of triggers include the creation of a pull request, the rejection of a code review, and more. [Send feedback on triggers](#).

Caveats: Conditions, validators, and permissions will be ignored for automatic transitions. Global transitions can be automated with triggers, but please read our guide first.

Not sure where to start? [Read our guide on configuring triggers](#).

Connect to Bitbucket, Stash, FishEye or Crucible to start using triggers.

[Add trigger](#)

Trigger	Details	Actions
There are no triggers currently defined.		

4. Select the trigger you want to add and click on the **Next** button.
5. Confirm the trigger source detected and click on the **Add trigger** button.

Adding a condition to transitions

New transitions do not have any conditions by default. This means that anyone who has access to the issue will be able to execute the transition. JIRA allows you to add any number of conditions to the transition:

1. Select the transition you want to add conditions to.
2. Click on the **Conditions** link.
3. Click on the **Add condition** link. This will bring you to the **Add Condition To Transition** page, which lists all the available conditions you can add:

The screenshot shows a user interface for managing conditions on a transition. At the top, there are tabs for 'Triggers' (0), 'Conditions' (1), 'Validators' (0), and 'Post Functions' (5). The 'Conditions' tab is selected. Below the tabs, a dropdown menu shows 'All of the following conditions'. To the right of the dropdown is a red-bordered 'Add condition' button. A note below the dropdown states: 'Only users with Resolve Issues permission can execute this transition.' The overall background is white with grey borders around the tabs and the main content area.

4. Select the condition you want to add.
5. Click on the **Add** button to add the condition.
6. Depending on the condition, you may be presented with the **Add Parameters To Condition** page where you can specify the configuration options for the condition. For example, the **User Is In Group** condition will ask you to select the group to check against, shown as follows:

The screenshot shows a dialog box titled 'Add Parameters To Condition'. It contains the instruction 'Add required parameters to the Condition.' Below this is a 'Group:' field with 'hr-team' selected. A tooltip for the field says 'The group membership to check.' At the bottom of the dialog are 'Add' and 'Cancel' buttons. The dialog has a light blue header bar and a white body with a thin grey border.

Newly added conditions are appended to the end of the existing list of conditions, creating a **condition group**. By default, when there is more than one condition, logical AND is used to group the conditions. This means that all conditions must pass for the entire condition group to pass. If one condition fails, the entire group fails, and the user will not be able to execute the transition. You can switch to use the logical OR condition, which means only one of the conditions in the group needs to pass for the entire group to pass. This is a very useful feature

as it allows you to combine multiple conditions to form a more complex logical unit.

For example, the **User Is In Group** condition lets you specify a single group, but with the **AND** operator, you can add multiple **User Is In Group** conditions to ensure that the user must exist in all the specific groups to be able to execute the transition. If you use the **OR** operator, then the user will only need to belong to one of the listed groups. The only restriction to this is that you cannot use both operators for the same condition group.

Note

One transition can only have one condition group, and each conditional group can only have one logical operator.

Adding a validator to transitions

Like conditions, transitions, by default, do not have any validators associated. This means that transitions are completed as soon as they are executed. You can add validators to transitions to make sure that executions are only allowed to be complete when certain criteria are met. Use the following steps to add a validator to a transition:

1. Select the transition you want to add conditions to.
2. Click on the **Validators** link.
3. Click on the **Add validator** link. This will bring you to the **Add Validator To Transition** page, which lists all the available validators you can add:

The screenshot shows a user interface for managing validators. At the top, there are tabs: Triggers (0), Conditions (1), Validators (1), and Post Functions (5). The Validators tab is selected. Below the tabs, a message says "The transition requires the following criteria to be valid". A red box highlights the "Add validator" button. Underneath, it says "Required fields: Resolution Details".

4. Select the validator you want to add.
5. Click on the **Add** button to add the validator.
6. Depending on the validator, you may be presented with the **Add Parameters To Validator** page where you can specify configuration options for the validator. For example, the **Permissions** validator will ask you to select the permission to validate against, shown as follows:

The screenshot shows a dialog box titled "Add Parameters To Validator". It has a sub-instruction "Add required parameters to the Validator.". Below is a "Permission:" dropdown menu set to "Administer Projects". A small note says "The permission to check." At the bottom are "Add" and "Cancel" buttons.

Similar to conditions, when there are multiple validators added to a transition, they form a **validator group**. Unlike conditions, you can only use the logical **AND** condition for the group. This means that in order to complete a transition, every validator added to the transition must pass its validation criteria. Transitions cannot selectively pass validations using the logical **OR**.

The following screenshot shows a validator (the **Field required** validator from JIRA Suite Utilities, refer to the *Extending workflow with workflow add-ons* section) being placed on the transition, which validates whether the user has entered a value for the **Resolution Details** field:

Resolve Issue

Resolving an issue indicates that the developers are satisfied the issue is finished.

Resolution*: Done

Resolution Details

Resolution Details is required.

field required validation error

Comment

Style

Resolve Cancel

This screenshot shows the 'Resolve Issue' dialog in JIRA. At the top, there's a note: 'Resolving an issue indicates that the developers are satisfied the issue is finished.' Below it, the 'Assignee' is set to 'Patrick Li'. The 'Resolution' dropdown is set to 'Done'. The 'Resolution Details' field is empty and highlighted with a red border, indicating a validation error. A red callout box points to this field with the text 'field required validation error'. Below the field, a message says 'Resolution Details is required.' To the left, there's a 'Comment' section with a rich text editor toolbar. At the bottom right are 'Resolve' and 'Cancel' buttons.

Adding a post function to transitions

Transitions, by default, are created with several post functions. These post functions provide key services to JIRA's internal operations, so they cannot be deleted from the transition. These post functions perform the following:

- Set the issue status to the linked status of the destination workflow step
- Add a comment to an issue if one is entered during a transition
- Update the change history for an issue and store the issue in the database
- Re-index an issue to keep indexes in sync with the database
- Fire an event that can be processed by the listeners

As you can see, these post functions provide some of the basic functions such as updating a search index and setting an issue's status after transition execution, which are essential in JIRA. Therefore, instead of letting users manually add them in and risk the possibility of leaving one or more out, JIRA adds them for you automatically when you create a new transition:

1. Select the transition you want to add post functions to.
2. Click on the **Post Functions** link.
3. Click on the **Add post function** link and select the post function you want to add:

The following will be processed after the transition occurs

- 1. Set issue status to the linked status of the destination workflow step.
- 2. Add a comment to an issue if one is entered during a transition.
- 3. Update change history for an issue and store the issue in the database.
- 4. Re-index an issue to keep indexes in sync with the database.
- 5. Fire a Issue Resolved event that can be processed by the listeners.

Add post function

4. Click on the **Add** button to add the post function.
5. Depending on the post function, you may be presented with the **Add Parameters To Function** page where you can specify configuration options for the post function. The following screenshot shows an example from the **Update Issue Field** post function:

Add Parameters To Function

Add required parameters to the Function.

Issue Field:

The field to change.

Field Value: Unassigned
 Automatic
 Start typing to get a list of possible matches.

Please make sure that the value you set is valid for the project using this workflow. Otherwise, the transition may fail at execution time.

Just like conditions and validators, multiple post functions form a post function group in a transition. After a transition is executed, each post function in the group is executed sequentially as it appears in the list, from top to bottom. If any post function in the group encounters an error during processing, you will receive an error, and the remaining post functions will not be executed.

Since post functions are executed sequentially and some of them possess the ability to modify values and perform other tasks, often, their sequence of execution becomes very important. For example, if you have a post function that changes the issue's assignee to the current user and another post function that updates an issue field's value with the issue's assignee, obviously the update assignee post function needs to occur first, so you need to make sure that it is above the other post function.

You can move the position of post functions up and down along the list by clicking on the **Move Up** and **Move Down** links. Note that not all post functions can be repositioned.

Updating an existing workflow

JIRA lets you make changes to both active and inactive workflows. However, with active workflows, there are several restrictions:

- Existing workflow steps cannot be deleted
- The associated status for an existing step cannot be edited
- If an existing step has no outgoing transitions, it cannot have any new outgoing transitions added

If you need to make these changes, you will have to either deactivate the workflow by removing the associations of the workflow with all projects or create a copy of the workflow.

Tip

You can always make a copy of the active workflow, make your changes, and then swap the original with the copied workflow in your workflow scheme.

When editing an active workflow, you are actually making changes to a draft copy of the workflow created by JIRA. All the changes you make will not be applied until you publish your draft.

Note

Do not forget to publish your draft after you have made your changes.

Publishing a draft is a very simple process. All you have to do is as follows:

1. Click on the **Publish Draft** button. You will be prompted if you would like to first create a backup of the original workflow. It is recommended that you create a backup in case you need to undo your changes.
2. Select either **Yes** or **No** to create a backup of the current workflow before applying the changes. This is a handy way to quickly create a backup if you have not made a copy already. If you do choose to create a backup, it is a good idea to name your workflow with a consistent convention (for example, based on a version such as `Sales Workflow 1.0`) to keep track of the changes.
3. Click on the **Publish** button to publish the draft workflow and apply changes, as shown in the following screenshot:

Publish Draft Workflow

You are about to publish the workflow **HD: Task Management Workflow (Draft)**. This will overwrite the active workflow **HD: Task Management Workflow** and remove the draft! Click Publish if you want to continue.

Save a backup copy? Yes

Workflow schemes

While workflows define and model business processes, there still needs to be a way to tell JIRA the situations in which to apply the workflows. As with other configurations in JIRA, this is achieved through the use of schemes. As we have seen in the previous chapters, schemes act as self-contained, reusable configuration units that associate specific configuration options with projects and, optionally, issue types.

A workflow scheme establishes the association between workflows and issue types. The scheme can then be applied to multiple projects. Once applied, the workflows within the scheme become active.

To view and manage workflow schemes, perform the following steps:

1. Log in as a JIRA administrator user.
2. Browse to the JIRA administration console.
3. Select the **Issues** tab and then the **Workflow Schemes** option. This will bring up the **Workflow Schemes** page, as shown in the following screenshot:

The screenshot shows the 'Workflow schemes' page in JIRA. At the top, there's a header with a '+ Add Workflow Scheme' button and a help icon. Below the header, a message states: 'Workflow Schemes allow you to define which workflows apply to given issue types and projects.' A 'Active' section is expanded, showing three rows of workflow schemes:

Name	Projects	Issue Type	Workflow	Operations
classic	Demonstration Project	<input type="checkbox"/> Unassigned Types →	classic default workflow	Edit · Copy
HD: Task Management Workflow Scheme	Help Desk	<input type="checkbox"/> Unassigned Types → <input checked="" type="checkbox"/> Story → <input checked="" type="checkbox"/> Bug →	HD: Task Management Workflow HD: Story Management Workflow HD: Bug Management Workflow	Edit · Copy
HR: Task Management Workflow Scheme	Human Resource	<input type="checkbox"/> Unassigned Types →	HR: Task Management Workflow	Edit · Copy

The **Workflow Schemes** page shows each scheme's workflow association. For example, in the preceding screenshot, we can see that for **HD: Task Management Workflow Scheme**, the issue type **Bug** is assigned with **HD: Bug Management Workflow**, while the issue type **Story** is assigned to **HD: Story Management Workflow**. It also shows what projects are using the workflow schemes.

Creating a workflow scheme

With JIRA 7, similar to other configuration schemes such as screen scheme, a new workflow scheme will be created when you create a new project, so normally you will not need to create new workflow schemes. However, there might be times such as when experimenting with changes to workflow that you still want to keep existing configurations untouched as a backup. To create a new workflow scheme:

1. Browse to the **Workflow Schemes** page.
2. Click on the **Add workflow scheme** button. This will take you to the **Add Workflow Scheme** dialog.
3. Enter a name and description for the new workflow scheme. For example, you can choose to name your workflow after the project/issue type it will be applied to.
4. Click on the **Add** button to create the workflow scheme.

You will be taken back to the **Workflow Schemes** page once the new scheme has been created, and it will be listed in the table of available workflow schemes.

When you first create a new workflow scheme, the scheme is empty. This means it contains no associations of workflows and issue types, except the default association called JIRA Workflow (jira). What you need to do next is configure the associations by assigning workflows to issue types.

Note

You can delete the default JIRA Workflow (jira) association after you have added an association yourself.

Configuring a workflow scheme

Workflow schemes contain associations between issue types and workflows. After you have created a workflow scheme, you need to configure and maintain the associations as your requirements change. For example, when a new issue type is added to the projects using the workflow scheme, you may need to add an explicit association for the new issue type.

To configure a workflow scheme, perform the following steps:

1. Browse to the **Workflow Schemes** page.
2. Click on the **Edit** link for the workflow scheme you want to configure. This will take you to the workflow's details page, as shown in the following screenshot:

The screenshot shows the configuration page for the 'HD: Task Management Workflow Scheme'. At the top, it says 'SHARED BY 1 PROJECT' and has a 'Click to add description' field. Below is an 'Add Workflow' button. The main area is a table with three columns: 'Workflow', 'Issue Types', and 'Operations'. It lists three workflows:

Workflow	Issue Types	Operations
HD: Task Management Workflow View as: Text · Diagram Task Management workflow	<input type="checkbox"/> All Unassigned Issue Types	Assign · Remove
HD: Bug Management Workflow View as: Text · Diagram Task Management workflow	<input checked="" type="checkbox"/> Bug ×	Assign · Remove
HD: Story Management Workflow View as: Text · Diagram Task Management workflow	<input type="checkbox"/> Story ×	Assign · Remove

From this page, you will be able to see a list of existing associations, create new associations for issue types, and delete associations that are no longer relevant.

Assigning an issue type to a workflow

Issue type and workflow have a many-to-one relationship. This means each issue type can be associated with one and only one workflow. One workflow can be associated with multiple issue types. This rule is applied on a per workflow scheme basis, so you can have a different association of the same issue type in a different workflow scheme.

When you add a new association, JIRA will list all the issue types and all available workflows. Once you have assigned a workflow to the issue type, it will not appear in the list again until you remove the original association.

Among the list of issue types, there is an option called **All Unassigned Issue Types**. This option acts as a catch-all option for issue types that do not have an explicit association. This is a very handy feature if all issue types in your project are to have the same workflow; instead of mapping them out manually one by one, you can simply assign the workflow to all with this option. This option is also important as new issue types are added and assigned to a project; they will automatically be assigned to the catch-all workflow. If you do not have an **All Unassigned Issue Types** association, new or unassigned issue types will be assigned to use the default basic **jira** workflow. As with normal issue types, you can have only one catch-all association.

Tip

If all issues types will be using the same workflow, use the **All Unassigned Issue Types** option.

There are two ways to assign a workflow to an issue type. If you want to add an issue type to one of the existing associations:

1. Browse to the workflow scheme's details page for the workflow scheme you want to configure by clicking on its **Edit** link.
2. Click on the **Assign** link for the association you want to add an issue type to.
3. Select the issue types to add from the **Assign Issue Type to Workflow** dialog.
4. Click on the **Finish** button.

If you want to create a new association from scratch:

1. Browse to the workflow scheme's details page for the workflow scheme you want to configure.
2. Select the **Add Existing** option from the **Add Workflow** menu. This will bring up the **Add Existing Workflow** dialog:

Add Existing Workflow

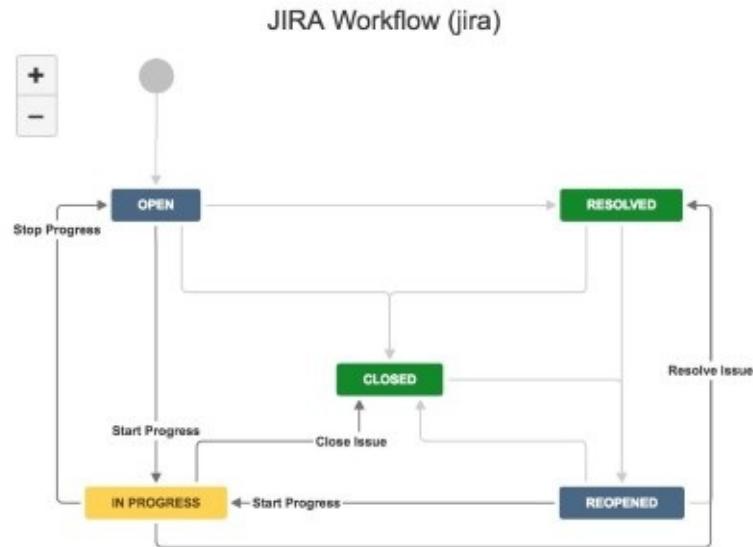

JIRA Workflow (jira)

classic default workflow

HR: Task Management Workflow

Sampel Workflow

Software Simplified Workflow for Project DEMO

Description The default JIRA workflow.

Last modified Never

[Next](#) [Cancel](#)

3. Select the workflow to use and click on the **Next** button.
4. Select the issue types to associate with the workflow and click on the **Finish** button. If you select an issue type that is already assigned, it will be removed from the old assignment and added to the currently selected workflow:

Assign Issue Types to "JIRA Workflow (jira)"

<input type="checkbox"/>  Issue Type	Currently Assigned Workflow
<input type="checkbox"/>  All Unassigned Issue Types	HD: Task Management Workflow
<input type="checkbox"/>  Bug	HD: Bug Management Workflow
<input type="checkbox"/>  Epic	
<input type="checkbox"/>  New Employee	
<input type="checkbox"/>  Story	HD: Story Management Workflow
<input checked="" type="checkbox"/>  Task	
<input type="checkbox"/>  Termination	
<input checked="" type="checkbox"/>  Sub-task	

[Back](#)

[Finish](#)

[Cancel](#)

Editing or deleting an association

Once you have associated an issue type to a workflow in a scheme, you cannot add a new association for the same issue type. There is also no edit option to change the association. What you need to do is to delete the existing association and create a new one using the following steps:

1. Browse to the workflow scheme's details page for the workflow scheme you want to configure.
2. Click on the **Remove** link for the association you want to remove.

Once an association is deleted, you will be able to create a new one for the issue type. If you do not assign a new workflow to the issue type, the workflow with the **All Unassigned Issue Types** option will be applied.

Applying a workflow scheme to projects

Workflow schemes are inactive by default after they are created. This means there are no projects in JIRA using the workflow scheme. To activate a workflow scheme, you need to select the scheme and apply it to the project.

When assigning a workflow scheme to a project, you need to follow the three basic steps:

1. Browse to the project administration page for the project you want to apply the workflow scheme to.
2. Select the **Workflows** option from the left panel.
3. Click on the **Switch Scheme** button.
4. Select the new workflow scheme to use and click on the **Associate** button.

On the confirmation page, depending on the differences between the current and new workflow, you will be prompted to make migration decisions for existing issues. For example, if the current workflow has a status called **Resolved** and the new workflow does not (or it has something equivalent but with a different ID), you need to specify the new status to place the issues that are currently in the **Resolved** status. Once mapped, JIRA will start migrating existing issues to the new status:

Associate Workflow Scheme to Project:

Step 2 of 3: The current status of each issue needs to be changed so that it is compatible with the new workflows.

Issue Type	Current Status	New Status
Epic 12	classic default workflow	HD: Task Management Workflow
	OPEN	→ To Do
	IN PROGRESS	→ To Do
	REOPENED	→ To Do
	RESOLVED	→ Done
	CLOSED	→ Done

1. Select new workflow statuses for the existing issues that are in statuses that do not exist in the new workflow.
2. Click on the **Associate** button to start the migration.

Once the migration starts, JIRA will display a progress bar showing you the progress.

Depending on the number of issues that need to be migrated, this process may take some time. It is recommended to allocate a time frame to perform this task as it can be quite resource-intensive for large instances.

Extending workflow with workflow add-ons

There are a number of very useful add-ons that will provide additional components such as conditions, validators, and post functions. The following list presents some of the most popular workflow-related plugins.

JIRA Suite Utilities

You can find a number of very useful conditions, validators, and post functions with this add-on. For example, the **Update Issue Field** post function that ships with JIRA allows you to update any issue fields such as priority and assignee when a workflow transition completes. The JIRA Suite Utilities plugin complements this by providing a very similar **Update Issue Custom Field** post function, which handles custom fields. There are many other useful components such as the **Copy Value From Other Field** post function, which will allow you to implement some amazing logic with your workflow. A must-have add-on for any JIRA. You can find out more at <https://marketplace.atlassian.com/plugins/com.googlecode.jira-suite-utilities>.

JIRA Workflow Toolbox

As the name suggests, it's a workflow toolbox with a rich set of workflow conditions, validators, and post functions. It intends to fill many gaps when developing complex workflows. For example, it provides a condition and validator that allows you to specify the checking rules with regular expressions. You can find out more at

<https://marketplace.atlassian.com/plugins/com.fca.jira.plugins.workflowToolbox.workflow-toolbox>.

JIRA Misc Workflow Extensions

This is another plugin with an assortment of conditions, validators, and post functions. Normal post functions let you alter the current issue's field values. This plugin provides post functions that will allow you to set a parent issue's field values from subtasks along with many other features. You can find out more at

[https://marketplace.atlassian.com/plugins/com.innovalog.jmwe.jira-misc-workflow-extensions.](https://marketplace.atlassian.com/plugins/com.innovalog.jmwe.jira-misc-workflow-extensions)

Workflow Enhancer for JIRA

This contains a variety of validators and conditions around comparisons of the value of a field with another field, and lets you set up validation logic to compare dates, numeric, and Boolean value, you can find out more at

<https://marketplace.atlassian.com/plugins/com.tng.jira.plugins.workflowenhancer>.

Script Runner

This is a very useful and powerful add-on that allows you to create your own custom conditions, validators, and post functions by writing scripts. This does require you to have some programming knowledge and a good understanding of JIRA's API. You can find out more at <https://marketplace.atlassian.com/plugins/com.onresolve.jira.groovy.groovyrunner>.

The HR project

We have seen the power of workflows and how we can enhance the usefulness of JIRA by adapting to everyday business processes. With our HR project, we have already defined two issue types to represent the onboarding and dismissing of an employee, both of these use the same default workflow with two steps, **To Do** and **Done**. So, we will now customize the workflow to represent a real-world HR process.

Our requirements for the business process would then include the following:

- The **New Employee** and **Termination** issue types will use customized workflow, while the **Task** issue type will continue to use the existing one.
- For **Termination** issue type, we will add two additional steps, one to conduct an exit interview, and one to ensure that all necessary company assets are returned.
- Ensure that only authorized personnel can transition the issue through the various statuses of the workflow.

The easiest way to implement these requirements would be to create a new workflow and add the additional process steps as new statuses. We will first do this to get our workflow structure in place. Later on, we will also look at how we can use other features in JIRA and incorporate them into our workflow to make it more robust.

Setting up workflows

The first step is to create a new workflow for our **Termination** issue type, since we still want to keep the existing workflow for the **Task** issue type. The easiest way to get started is to clone the current workflow to save us some time:

1. Browse to the **View Workflows** page.
2. Click on the **Copy** link for the **HR: Task Management Workflow** workflow.
3. Name the new workflow **HR: Termination Workflow**.
4. Click on the **Copy** button to create our workflow.

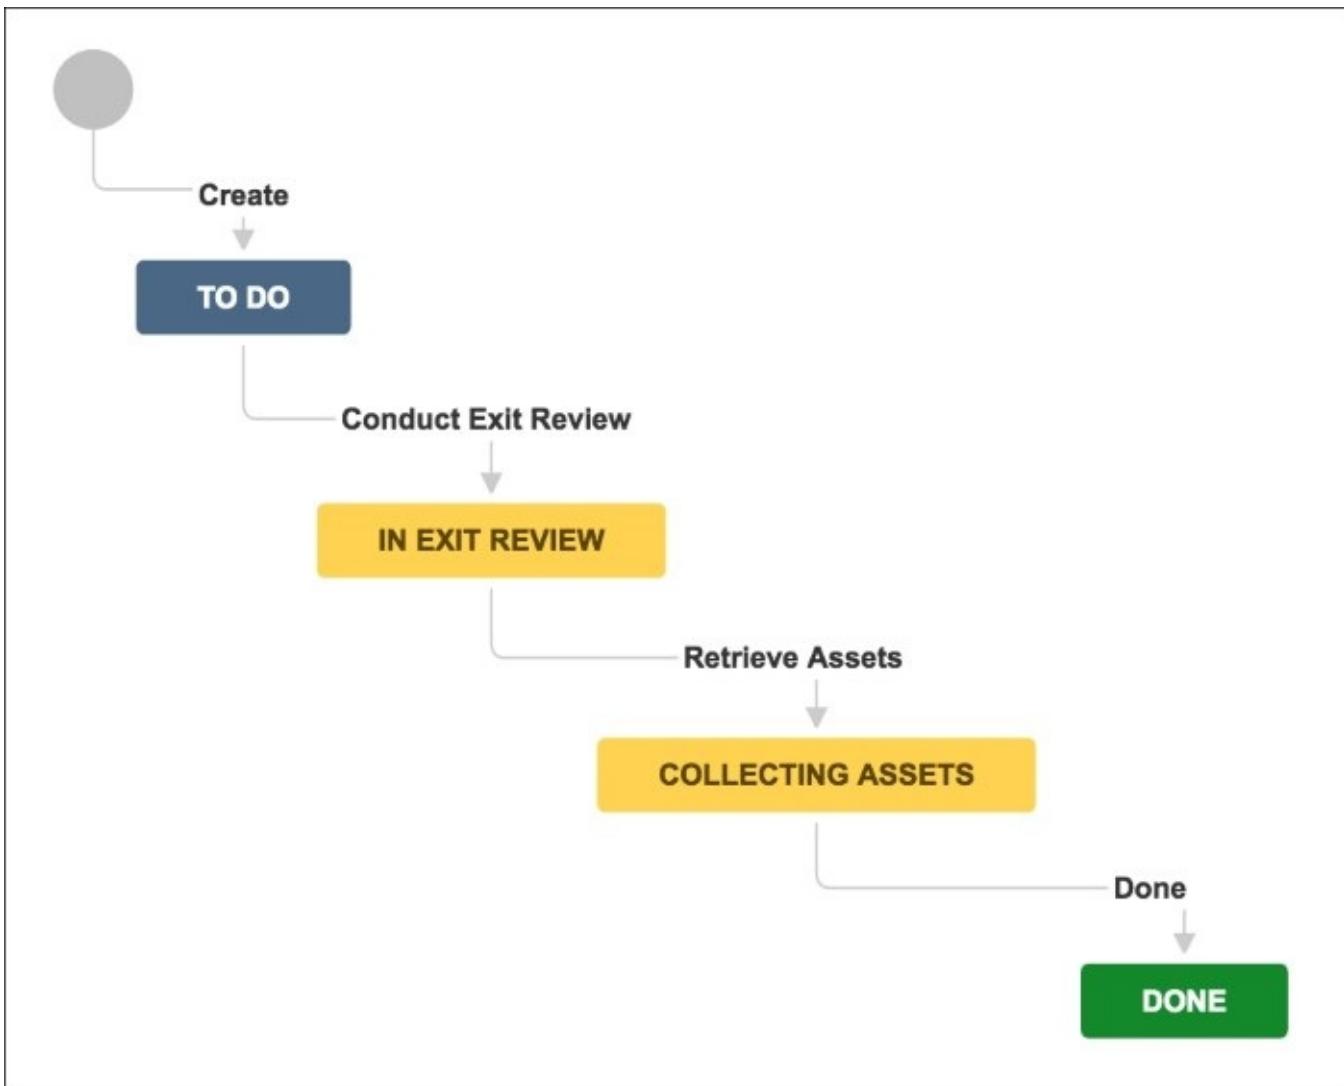

The next step is to add in the extra status we need. Make sure that you are in the workflow designer by selecting the **Diagram** option:

1. Click on the **Add status** button.
2. Enter the name for our new status as, **In Exist Review**, set the **Category** to **In Progress**, and click on **Add**. You will need to hit the **Enter** key on your keyboard, since we are creating a new status.
3. Click on the **Create** button to create the workflow status.
4. Repeat steps 2 and 3 to create a new status called **Collecting Assets**.

Now that we have our statuses added to our workflow, we need to connect them into the workflow with transitions. For now, we will make the workflow to go in a sequence in the order of **To Do | In Exit Review | Collecting Assets | Done**. Let's start with creating a transition going from **To Do | In Exit Review**:

1. Click on the **Add transition** button.
2. Select **To Do** as the **From status**.
3. Select **In Exit Review** as the **To status**.
4. Name the new transition as **Conduct Exit Review**.
5. Select **Workflow Screen** for **Screen**.
6. Click on the **Add** button to create the transition.
7. Repeat steps 1 to 6 to create two more transitions, linking **In Exit Review** to **Collecting Assets**, and **Collecting Assets** to **Done**.
8. With the new transitions in place, we will also want to remove the existing transitions between **To Do** and **Done**. So people cannot skip the process steps.

Your workflow will look something like the one shown in the following screenshot. You can rearrange the elements in the workflow to make the diagram flow more naturally:

The next customization we will do is to make sure that only authorized personnel can transition the issue along the workflow. For now, we will set it so only members of the `jira-administrators` group can transition an issue after it is created. Once we cover [Chapter 9, Securing JIRA](#), we can change this security setting:

1. Click on the `Conduct Exit Review` transition and click on **Conditions** from the transition property section.
2. Click on the **Add condition** button to bring up the **Add Condition To Transition** page.
3. Select the **User Is In Group** option.
4. Select the `jira-administrator` group.
5. Click on **Add** to add the condition to the transition.
6. Repeat steps 1 to 5 on the remaining transitions.

Using the **Users Is In Group** option will ensure that only users in the selected group, `jira-administrator` in this case, will see the transition with the condition applied to it.

Applying the workflow

With our workflow in place and set up, we need to let JIRA know the issue types that will be using our new workflow. Since we already have a workflow scheme in place for our project, we just need to associate the appropriate issue type to the workflow:

1. Browse to the **Workflow Schemes** page.
2. Click on the **Edit** link for **HR: Task Management Workflow Scheme**.
3. Click on the **Add Workflow** menu and select the **Add Existing** option.
4. Select our new **HR: Termination Workflow** option and click on the **Next** button.
5. Select the **Termination** issue type.
6. Click on **Finish** to create the association.
7. Click on the **Publish** button to apply the change.

This associates our new workflow with the **Termination** issue type specifically created for our HR project and leaves the default workflow for the others.

Putting it together

With our new workflow in place, we can now create a new **Termination** issue and start testing our implementation. Since we need to simulate a scenario where an "unauthorized user" cannot transition the issue after it is created, we need to create a new user. We will look at user management and security in [Chapter 9, Securing JIRA](#). For now, we will simply add a new user to our system:

1. Browse to the JIRA administration console.
2. Select the **Users management** tab and click on the **Users** link.
3. Click on the **Create user** button to bring up the **Create New User** dialog.
4. Name the new user `john.doe` (John Doe).
5. Set the password and e-mail address for this new user.
6. Uncheck the **Send Notification Email** option.
7. Check the **JIRA Software** option for **Application access**.
8. Click on the **Create** button to create the user.

Now, log in to JIRA as a new business user, `john.doe`, and create a new termination issue. After you create the issue, you will notice that you cannot execute any transitions. This is because you (`john.doe`) are not in the `jira-administrators` group, and you are currently, on the administrator user we created in [Chapter 1, Getting Started with JIRA](#), is in the `jira-administrators` group, so let's log in as the administrator. Once logged in as the administrator, you will see our new transition **Conduct Exit Interview**, as shown in the following screenshot:

The screenshot shows a JIRA issue page for an HR project. The title is "Employee Tom Johnson leaving". The issue type is "Termination" (indicated by a red square icon) and the priority is "Medium". The status is "TO DO (View Workflow)" and the resolution is "Unresolved". There is no assignee assigned. The description states: "Tom Johnson is leaving the company, his last day will be Dec 12th, 2016." The page includes standard JIRA navigation buttons like Edit, Comment, Assign, More, Conduct Exit Review, and Admin.

You will also see that, if you create a new task in the HR project, the task issue will continue to use the default workflow.

With the current workflow setup, everything happens in a sequential order. However, sometimes, you might need things to happen in parallel. For example, in the collecting assets step, there might be multiple assets to be collected for various teams, such as a laptop for IT and key card for security. It will be a lot more efficient if you can perform them at the same time and be able to track them individually. One way you can do this is by creating subtasks for each asset under the issue (remember, an issue can only be assigned to one person), and assign the subtask to the relevant team such as IT and security, so they can chase up with the employee to retrieve the asset. You can then set a condition on the **Done** transition to make sure that all subtasks are completed before they can be executed.

This can be expanded upon to have asset collection and exit interview as subtasks so that both can happen at the same time, and you can create different subtask issue types to differentiate them, as covered in [Chapter 4, Issue Management](#). Your termination issue may look something like this:

The screenshot shows a Jira issue page for 'Employee Tom Johnson leaving'. At the top, there's a navigation bar with 'Human Resource / HR-2' and a profile icon. Below it is the main title 'Employee Tom Johnson leaving'. A toolbar contains 'Edit', 'Comment', 'Assign', 'More', 'Close' (which is highlighted with a red box), and 'Admin'. A note 'only available if all sub-tasks are done' is displayed above the details section. The 'Details' section includes fields for Type (Termination), Priority (Medium), Labels (None), Status (TO DO), and Resolution (Unresolved). In the 'Description' section, it says 'Tom Johnson is leaving the company, his last day will be Dec 12th, 2016.' The 'Sub-Tasks' section lists three tasks: 1. 'Conduct exit interview for Tom' (status: DONE, assigned to Patrick Li), 2. 'Collect employee key card' (status: DONE, assigned to Kim Lee), and 3. 'Collect employee laptop' (status: DONE, assigned to John Stein).

Sub-Task	Status	Assigned To
1. Conduct exit interview for Tom	DONE	Patrick Li
2. Collect employee key card	DONE	Kim Lee
3. Collect employee laptop	DONE	John Stein

Summary

In this chapter, we looked at how JIRA can be customized to adapt to your organization. At the heart of this powerful feature is a robust workflow system that allows you to model JIRA workflows based on existing business processes. We also looked at the various components within a workflow, how to perform validations, and how post-processing provides a level of process automation.

In the next chapter, we will look at how we can combine the power of workflow and its event-driven system to facilitate communication through JIRA notifications and the e-mail system.

Chapter 8. E-mails and Notifications

So far, you have learned how to use and interact with JIRA directly from its web interface through a browser. However, you are not restricted only to a web browser; you can also communicate with JIRA through e-mails.

One powerful feature of JIRA is its ability to update users on their issues' progress through e-mails, and also create and comment on issues based on e-mails sent from users. This provides you with a whole new option of how you and your users can interact with JIRA. By the end of this chapter, you will have learned the following:

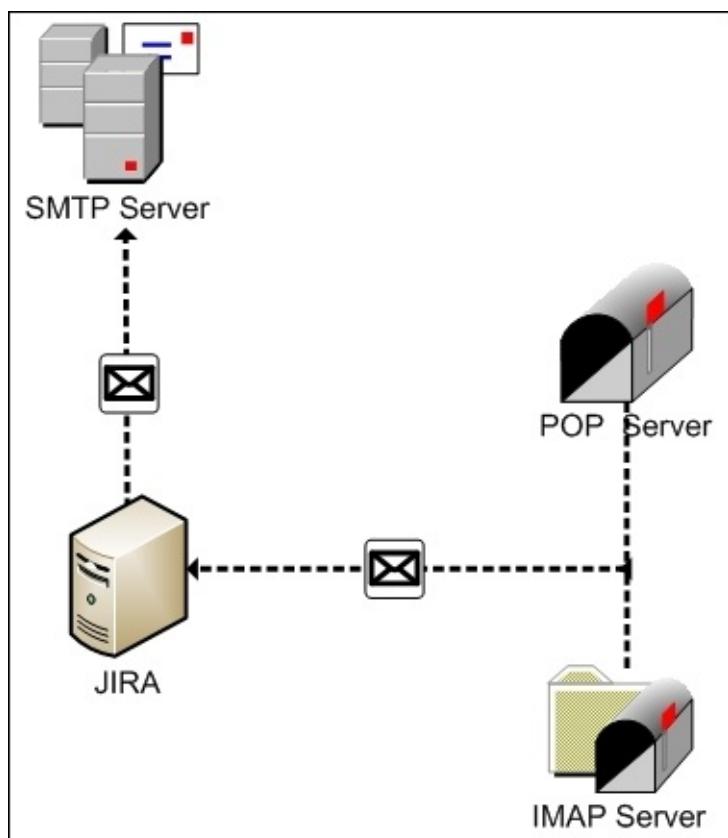

- How to set up a mail server in JIRA
- Events and how they are related to notifications
- How to configure JIRA to send out notifications based on events
- How to create custom mail templates
- What a mail handler is
- How to create issues and comments by sending e-mails to JIRA

JIRA and e-mail

E-mails have become one of the most important communication tools in today's world. Businesses and individuals rely on e-mails to send and receive information around the world almost instantly. Therefore, it comes as no surprise that JIRA is fully equipped and integrated with e-mail support.

JIRA's e-mail support comes in several flavors. Firstly, JIRA e-mails users about changes made to their issues, so people working on the same issue can be kept on the same page. Secondly, JIRA can also poll mailboxes for e-mails and create issues and comments based on their content. The last feature is the ability for users to create and subscribe to filters to set up feeds in JIRA (we will discuss filters in [Chapter 10, Searching, Reporting, and Analysis](#)). These features open up a whole new dimension on how users can interact with JIRA.

In the following sections, we will look at what you need to do to enable JIRA's powerful e-mail support and also explore the tools and options at your disposal to configure JIRA to e-mail it your way. The following figure shows how JIRA interacts with various mail servers:

Mail servers

In order for JIRA to communicate with e-mails, you need to configure or register your mail servers in JIRA. There are two types of mail servers you need to configure:

- **Outgoing:** This is used by JIRA to send e-mails out to users. JIRA supports SMTP mail servers.
- **Incoming:** This is used by JIRA to retrieve e-mails from users. JIRA supports POP or IMAP servers.

We will start with outgoing mail servers first to see how we can configure JIRA to send e-mails to users as well as customize the e-mail contents.

Working with outgoing mail

Like many settings in JIRA, you need to be a JIRA system administrator (the user created during the initial setup is a system administrator) to configure mail server details. Perform the following steps to manage the outgoing mail server:

1. Log in to JIRA as a JIRA administrator.
2. Browse to the JIRA administration console.
3. Select the **System** tab and then the **Outgoing Mail** option. This will bring up the **Outgoing Mail** page:

The screenshot shows the 'Outgoing Mail' configuration page. At the top, there is a status indicator 'ENABLED' with a 'Disable Outgoing Mail' button. Below this, the section title 'SMTP Mail Server' is displayed. A note states: 'The table below shows the SMTP mail server currently configured for JIRA.' A table lists the configuration details for the 'Local Mail Server':

Name	Details	Operations
Local Mail Server	From: support@appfusions.com Prefix: [JIRA] Host: localhost SMTP Port: 25	Edit · Delete · Send a Test Email

Note

You can have only one outgoing mail server in JIRA.

Adding an outgoing mail server

There are two ways of adding an outgoing mail server in JIRA; both options have some common configuration parameters that you will need to fill in. The following table shows these parameters:

Field	Description
Name	This specifies a name for the mail server.
Description	This specifies a brief description for the mail server.
From address	This specifies an e-mail address that outgoing e-mails will appear to have come from.
Email prefix	This specifies a prefix that will appear with all the e-mails sent from JIRA. This allows your users to set up filter rules in their mail clients. The prefix will be added to the beginning of the e-mail subject.
Service Provider	Select from one of the three predefined mail providers such as Google, Yahoo!, or the custom SMTP server.
Host Name	This specifies the host name of your mail server (for example, smtp.example.com).
SMTP Port	This specifies the port number that your mail server will be running on. This is optional; if left blank, the default port number 25 will be used.
Username	This is used to authenticate against the mail server if required. Note that mail servers may require authentication to relay e-mails to nonlocal users.
Password	This is used to authenticate the user against the mail server, if required.
JNDI Location	This is the JNDI lookup name if you already have a mail server configured for your application server. Refer to the following section for details.

For the rest of the parameters, depending on which option you select to set up your mail

server, you only need to fill in the ones that are appropriate.

The first option is to select from one of the built-in service providers and specify the mail server's details. For example, if you have an SMTP mail server running, you can select the **Custom** option from the **Service Provider** field and specify the host and port number. This is the approach most people will use, as it is simple and straightforward. With this approach, the administrator fills in the mail server's host information, such as the host name and port number:

1. Browse to the **Outgoing Mail** page.
2. Click on the **Configure new SMTP mail server** button.
3. Enter the general details of your mail server, including the name, description, from address, and e-mail prefix.
4. Select the type of mail server from the **Service Provider** field.
5. Enter the mail server's connection details.
6. Click on the **Test Connection** button to verify the configuration.
7. Click on the **Add** button to register to the mail server:

Add SMTP Mail Server

Use this page to add a new SMTP mail server. This server will be used to send all outgoing mail from JIRA.

Name *

The name of this server within JIRA.

Description

From address *

The default address this server will use to send emails from.

Email prefix *

This prefix will be prepended to all outgoing email subjects.

Server Details

Enter either the host name of your SMTP server or the JNDI location of a javax.mail.Session object to use.

SMTP Host

Service Provider

Protocol

Host Name *

The SMTP host name of your mail server.

SMTP Port

Optional - SMTP port number to use. Leave blank for default (defaults: SMTP - 25, SMTPS - 465).

Timeout

Timeout in milliseconds - 0 or negative values indicate infinite timeout. Leave blank for default (10000 ms).

TLS.

Optional - the mail server requires the use of TLS security.

Username

Optional - if you use authenticated SMTP to send email, enter your username.

Password

Optional - as above, enter your password if you use authenticated SMTP.

or

JNDI Location

JNDI Location

The JNDI location of a javax.mail.Session object, which has already been set up in JIRA's application server.

Tip

JIRA comes with support for Google and Yahoo! mail services. You can select these options in the **Service Provider** field if you are using these services.

The second option is to use **JNDI**. This approach is slightly more complicated as it requires configuration on the application server itself, and it requires you to restart JIRA.

If you are using the standalone distribution, which uses Apache Tomcat, the JNDI location will be `java:comp/env/mail/JiraMailServer`. You will also need to specify the mail server

details as a JNDI resource in the server.xml file in the JIRA_INSTALL/conf directory.

A sample declaration for Apache Tomcat is shown in the following code snippet. You will need to substitute some values with the real values for some of the parameters in the code of your mail server's details:

```
<Resource name="mail/JiraMailServer"
  auth="Container"
  type="javax.mail.Session"
  mail.smtp.host="mail.server.host"
  mail.smtp.port="25"
  mail.transport.protocol="smtp"
  mail.smtp.auth="true"
  mail.smtp.user="username"
  password="password"
/>
```

You will need to restart JIRA after saving your changes to the server.xml file.

Disabling outgoing mail

If you are running a test or evaluation JIRA instance or testing changes to notification rules, you might not want to flood your users with test e-mails. The easiest way for you to disable all outgoing e-mails is by just clicking on the **Disable Outgoing Mail** button. Once you are ready to send e-mails again, you can click on the **Enable Outgoing Mail** button.

Note

Disabling outgoing mail will only prevent JIRA from sending out notification e-mails based on notification schemes.

Enabling SMTP over SSL

To increase security, you can encrypt the communication between JIRA and your mail server if your mail server supports SSL. There are two steps involved in enabling SSL over SMTP in JIRA.

The first step is to import your mail server's SSL certificate into Java's trust store. You can do this with Java's keytool utility. On a Windows machine, run the following command in Command Prompt:

```
Keytool -import -alias mail.yourcompany.com -keystore  
$JAVA_HOME/jre/lib/security/cacerts -file yourcertificate
```

The second step is to configure your application server to use SSL for mail communication. The following declaration is for Apache Tomcat that is used by JIRA Standalone. We use the same configuration file and only need to add two additional parameters:

```
<Resource name="mail/JiraMailServer"  
auth="Container"  
type="javax.mail.Session"  
mail.smtp.host="mail.server.host"  
mail.smtp.port="25"  
mail.transport.protocol="smtp"  
mail.smtp.auth="true"  
mail.smtp.user="username"  
password="password"  
mail.smtp.starttls.enabled="true"  
mail.smtp.socketFactory.class="javax.net.ssl.SSLSocketFactory"  
/>
```

Once you import your certificate and configure your mail server, you will have to restart JIRA.

Sending a test e-mail

It is always a good idea to send a test e-mail after you configure your SMTP mail server to make sure that the server is running and you have set it correctly in JIRA:

1. Browse to the **Outgoing Mail** page.
2. Click on the **Send a Test Email** link for your SMTP mail server.
3. Click on the **Send** button to send the e-mail. JIRA will autofill the **To** address based on the user you are logged in as.

If everything is correct, you will see a confirmation message in the **Mail log** section and receive the e-mail in your inbox. If there are errors, such as mail server connection, then the **Mail log** section will display the problems. This is very useful when troubleshooting any problems with JIRA's connectivity with the SMTP server:

The screenshot shows two parts of a JIRA interface. The top part is a 'Send email' dialog with fields for To (patrick@appfusions.com), Subject (Test Message From JIRA), and Message Type (Text). The Body field contains a test message with details about the server setup. Below this is an 'SMTP logging' checkbox (unchecked) with a 'Log SMTP-level details' link. The bottom part is a 'Mail log' section showing a log entry with an error message about failing to connect to the host. A note at the bottom says 'Log of the events for sending mail.'

Send email

You can send a test email here.

To: patrick@appfusions.com

Subject: Test Message From JIRA

Message Type: Text

Body:

```
This is a test message from JIRA.  
Server: Local Mail Server  
SMTP Port: 25  
Description:  
From: support@appfusions.com  
Host User Name: null
```

SMTP logging Log SMTP-level details

Send **Cancel**

Mail log

Log:

```

Log of the events for sending mail.

In the preceding screenshot, you can see the test e-mail delivery has failed, and the error is

because JIRA was unable to connect to the configured SMTP server.

Mail queues

E-mails in JIRA are not sent immediately when an operation is performed. Instead, they are placed in a mail queue, which JIRA empties periodically (every minute). This is very similar to the real-life scenario, where e-mails are placed in mailboxes and picked up every day.

Viewing the mail queue

Normally, you do not need to manage the mail queue. JIRA automatically places e-mails into the queue and flushes them periodically. However, as an administrator, there may be times when you wish to inspect the mail queue, especially to troubleshoot problems related to JIRA notification e-mails. Sometimes, e-mails can get stuck for a number of reasons and inspecting the mail queue will help you identify the problems and fix them.

Perform the following steps to view the content of the mail queue:

1. Browse to the JIRA administration console.
2. Select the **System** tab and then the **Mail queue** option.

Mail Queue

This page shows you the current JIRA internal event queue, whose events may trigger notification emails.
Warning: Sending mail is disabled.

The queue currently has 3 items in it.

Flush mail queue - this will send all mail in the queue immediately.

Mail Queue (3) **Error Queue (0)**

Subject	Queued
(DEMO-3) Keyboard shortcuts	11/Dec/14 7:36 PM
(DEMO-1) What is an issue?	11/Dec/14 7:36 PM
(DEMO-2) Changing an issue's status	11/Dec/14 7:36 PM

This page provides you with a one-page view of the current e-mails in the queue waiting for delivery. There are two queues: the main mail queue and the error queue.

The **Mail Queue** tab contains all the e-mails that are pending to be delivered. If JIRA is able to successfully deliver these e-mails, they will be removed from the queue. Items listed in red indicate that JIRA has unsuccessfully attempted to send those e-mails. JIRA will retry 10 times, and if still unsuccessful, these items will be moved to the error queue.

The **Error Queue** tab contains e-mails that cannot be delivered by JIRA. You can choose to resend all the failed items in the error queue or delete them.

Flushing the mail queue

While JIRA automatically flushes the mail queue, you can also manually flush the queue if it gets stuck or to send out e-mails immediately. When you manually flush the queue, JIRA will try to send all the e-mails that are currently in the queue.

Perform the following steps to manually flush the mail queue:

1. Browse to the **Mail Queue** page.
2. Click on the **Flush mail queue** button.

If JIRA is successful in sending e-mails, you will see the queue shrink and the items disappear. If some e-mails fail to be delivered, those items will be highlighted in red.

Manually sending e-mails

Sometimes, you, as the administrator, may need to send out e-mails containing important messages to a wide audience. For example, if you are planning some maintenance work that will take JIRA offline for an extended period of time, you may want to send an e-mail to all JIRA users to let them know of the outage.

JIRA has a built-in facility, where you can manually send out e-mails to specific groups of users. There are two options when manually sending e-mails—you can either send them based on groups or by projects.

When sending by groups, all you have to do is select one or more groups in JIRA, and all users that belong to the selected groups will receive the e-mail. Users belonging to more than one group will not get duplicated e-mails.

When sending e-mails by projects, you have to first select one or more projects and then the project roles. We will discuss project roles in more detail in the next chapter; for now, you can think of them as groups of users within projects. For example, you can send e-mails to all users that are a part of the demonstration project rather than all users in JIRA.

To send e-mails to users in JIRA, perform the following steps:

1. Browse to the JIRA administration console.
2. Select the **System** tab and then the **Send email** option.
3. Choose if you want to send to users by **Project Roles** or **Groups**.
4. Enter the e-mail's subject and body content.
5. Click on the **Send** button to send the e-mail to all users in the selected project roles/groups.

The following screenshot shows an example of sending maintenance outage notification e-mails to everyone by selecting the **jira-software-users** group, which every JIRA Software user is a member of by default:

Send email

You can send an email to JIRA users here.

Please select one or more groups or project roles from the list below. The email message will be sent to all members of the chosen groups or project roles.

Note: a user will receive the email only once, even if they are a member of more than one group or project role.

From support@appfusions.com

To * Project Roles Groups

Groups:
jira-administrators
jira-software-users

Reply To no-reply@company.com

Optionally, specify the 'Reply-To' address.

Subject * JIRA maintenance notification

Body * Hi everyone,

JIRA will be taken down today after 6PM PST for maintenance. The expected outage will be around 1 hour. Please make sure you save all your work.

IT team

The body of the email message. You may include HTML.

Message Type

The content-type of the email message.

Bcc

Check this box if you want to hide the users email address.

Tip

Since JIRA does not provide a **What You See Is What You Get (WYSIWYG)** editor for composing e-mails, you may want to draft an e-mail and send it to yourself before sending it out to everyone.

Events

JIRA is an event-driven system. This means that usually when an action occurs (for example, when an issue is created), JIRA fires off a corresponding event. This event is then picked up by components that are designed to listen to the event. Not surprisingly, they are called **listeners**. When a listener picks up an event, it will perform its duty such as keeping issues up-to-date with changes or sending an e-mail to users watching the issue.

This mechanism allows JIRA to process operations asynchronously. The advantage of this model is operations, such as sending e-mails, and it's separated from JIRA's core functions such as issue creation. If there is a problem with the mail server, for example, you will not want this problem to prevent your users from creating issues.

There are two types of events in JIRA:

- **System events:** These are internal events used by JIRA, and they usually represent the main functionalities in JIRA. They cannot be added, edited, or deleted.
- **Custom events:** These are events created by users. They can be added and deleted, and they are fired through workflow post functions.

The following table lists all the system events in JIRA and what they are used for:

Event	Description
Issue Created	This states that an issue has been created in JIRA.
Issue Updated	This states that an issue has been updated (for example, changes to its fields).
Issue Assigned	This states that an issue has been assigned to a user.
Issue Resolved	This states that an issue has been resolved (usually applied to the resolve workflow transition).
Issue Closed	This states that an issue has been closed (usually applied to the closed workflow transition).
Issue Commented	This states that a comment has been added to an issue.
Issue	

Comment Edited	This states that a comment has been updated.
Issue Reopened	This states that an issue has been reopened (usually applied to the reopen workflow transition).
Issue Deleted	This states that an issue has been deleted from JIRA.
Issue Moved	This states that an issue has been moved (to a different or the same project).
Work Logged On Issue	This states that the time has been logged on this issue (if time tracking has been enabled).
Work Started On Issue	This states that the assignee has started working on this issue (usually applied to the start progress workflow transition).
Work Stopped On Issue	This states that the assignee has stopped working on this issue (usually applied to the stop progress workflow transition).
Issue Worklog Updated	This states that the worklog has been updated (if time tracking has been enabled).
Issue Worklog Deleted	This states that the worklog has been deleted (if time tracking has been enabled).
Generic Event	This states a generic event that can be used by any workflow post function.
Custom Event	This states that the events created by the user to represent arbitrary events generated by business processes.

As an administrator, you will be able to get a one-page view of all the events in JIRA. You just need to do the following:

1. Browse to the JIRA administration console.
2. Select the **System** tab and then the **Events** option. This will bring up the **View Events** page.

Each event is associated with a template, often referred to as a mail template. These templates

define the content structure of e-mails when notifications are sent. For system events, you cannot change their templates (you can change the template files, however). For custom events, you can choose to use one of the existing templates or create your own mail template.

In the following sections, we will first look at how to create and register custom mail templates, create a new custom event to use the new template, and fire the new event when actions are performed on an issue. After that, we will look at how to tie events to notifications, so we can tell JIRA who should receive notification e-mails for the event.

Adding a mail template

Mail templates are physical files that you create and edit directly via a text editor; you cannot edit mail templates in the browser. Each mail template is made up of three files:

- **Subject template:** This file contains the template used to generate the e-mail's subject
- **Text template:** This file contains the template used by JIRA when the e-mail is sent as plain text
- **HTML template:** This file contains the template used by JIRA when the e-mail is sent as HTML.

Mail templates are stored in the <JIRA_INSTALL>/atlassian-jira/WEB-INF/classes/templates/email directory. Each of the three files listed are placed in their respective directories called subject, text, and html.

While creating new mail templates, it is a good practice to name your template files after the issue event. This will help future users understand the purpose of the templates.

Mail templates use Apache's Velocity template language (<http://velocity.apache.org>). For this reason, creating new mail templates will require some understanding of HTML and template programming.

If your templates only contain static text, you can simply use standard HTML tags for your template. However, if you need to have dynamic data rendered as part of your templates, such as the issue key or summary, you will need to use the **Velocity syntax**. A full explanation of Velocity is beyond the scope of this book. The following section provides a quick introduction to creating simple mail templates for JIRA. You can find more information on Velocity and its usage in JIRA mail templates at <https://confluence.atlassian.com/x/dQISCw>.

In a Velocity template, all the text will be treated as normal. Anything that starts with a dollar sign (\$), such as \$issue, is a Velocity statement. The \$ sign tells Velocity to reference the item after the sign, and when combined with the period (.), you are able to retrieve the value specified. For example, the following code in a template will get the issue key and summary from the current issue, separated by a - character:

```
$issue.key - $issue.summary
```

This would produce content similar to DEMO-1 - This is a demo issue.

JIRA provides a range of velocity references that you can use for creating mail templates. These references allow you to access data such as the issue being updated and the user triggering the event. You can find a comprehensive list at <https://developer.atlassian.com/display/JIRADEV/Velocity+Context+for+Email+Templates>.

Now that you have a brief understanding of how Velocity works, you first need to create a template for the mail subject. The following code shows a typical subject template:

```
$eventType: ($issue.key) $issue.summary
```

When the template is processed, JIRA will substitute the actual values for the event type (for example, **Issue Created**), issue key, and issue summary. So the preceding example would produce content similar to Issue Escalated: HD-11: Database server is running very slow.

You then need to create a template for the actual e-mail content. You need to create a text and HTML version. The following code shows a simple example of a text-based template, which displays the key for the escalated issue:

Hello,

The ticket \$issue.key has been escalated and is currently being worked on. We will contact you if we require more information.

Regards
Support team.

Before JIRA sends out the e-mail, the preceding text will be processed, where all Velocity references, such as \$issue.key, will be converted into proper values, for example, DEMO-1.

After creating your mail templates, register them with JIRA. To register your new templates, locate and open the `email-templates-id-mappings.xml` file in the `<JIRA_INSTALL>/atlassian-jira/WEB-INF/classes` directory in a text editor. Add a new entry to the end of the file before closing the `</templatemappings>` tag, as follows:

```
<templatemapping id="10001">
  <name>Example Custom Event</name>
  <template>examplecustomevent.vm</template>
  <templatetype>issueevent</templatetype>
</templatemapping>
```

Here, we register a new custom mail template entry and the details are given in the following table:

Parameter	Description
id	This is the unique ID for the template. You need to make sure that no other template mapping has the same ID.
name	This is a human-readable name for JIRA to display.
template	These are the mail template file names for subject, text, and HTML. All three template files must be named as specified here.

type

This is the template type. For events generated from an issue, the value will be issueevent.

After creating your templates and registering them in the mapping file, you will have to restart JIRA for the changes to be picked up. The new templates will be available when we create new events, as covered in the following section.

Adding a custom event

JIRA comes with a comprehensive list of system events focused around issue-related operations. However, there will be times when you will need to create custom-designed events representing specialized business operations, or when you simply need to use a custom e-mail template.

Perform the following steps to add a new custom event:

1. Browse to the **View Events** page.
2. Enter a name and description for the new event in the **Add New Event** section.
3. Select the mail template for the new event.
4. Click on the **Add** button to create a new event:

Add New Event

Add a new event with a description and a default email template.

Name	Generic Example Event
Description	This is an example event.
Template	Generic Event

Select the default email template for this event.

Add

Firing a custom event

Unlike system events, with custom events, you need to tell JIRA when it can fire a custom event.

Custom events are mostly fired by workflow transitions. If you recall from [Chapter 7, Workflow and Business Process](#), you can add post functions to workflow transitions. Almost all of JIRA's transitions will have a post function that fires an appropriate event. It is important to understand that just because an event is fired does not mean that there needs to be something to listen to it.

If you skipped [Chapter 7, Workflow and Business Process](#), or still do not have a good understanding on workflows, now is be a good time to go back and revisit the chapter.

Perform the following steps to fire a custom event from a workflow post function:

1. Browse to the **View Workflows** page.
2. Click on the **Edit** link for the workflow that will be used to fire the event.
3. Click on the transition that will fire the event when executed.
4. Click on the **Post Functions** tab.
5. Click on the **Edit** link for the post function that reads `Fire a <event name> event that can be processed by the listeners:`

Transition: Resolve Issue

[Edit](#)[View Properties](#)[Delete](#)

Screen: Resolve Issue Screen

Triggers 0

Conditions 1

Validators 0

Post Functions 5

The following will be processed after the transition occurs

[Add post function](#)

1. Set issue status to the linked status of the destination workflow step.
2. Add a comment to an issue if one is entered during a transition.
3. Update change history for an issue and store the issue in the database.
4. Re-index an issue to keep indexes in sync with the database.
5. Fire a **Issue Resolved** event that can be processed by the listeners.

6. Select the custom event from the drop-down list.
7. Click on the **Update** button to apply the changes to the post function.
8. Publish the workflow.

Now, whenever the workflow transition is executed, the post function will run and fire the selected event. Each transition can fire only one event, so you cannot have both **Issue Created** and **Issue Updated** events being fired from the same transition.

Notifications

Notifications associate events (both system and custom) to e-mail recipients. When an event is fired and picked up, e-mails will be sent out. Notification types define recipients of e-mails. For example, you can set them to only send e-mails to a specific user or all members from a given user group. You can add multiple notifications to a given event.

JIRA ships with a comprehensive list of notification types (that is, the recipients) that will cover many of your needs. The following table lists all the notification types available and how they work:

Notification type	Description
Current Assignee	This is the current assignee of the issue.
Reporter	This is the reporter of the issue (usually the person who originally created the issue).
Current User	This is the user who fired the event.
Project Lead	This is the lead of the project the issue belongs to.
Component Lead	This is the lead of the component the issue belongs to.
Single User	This states that any user that exists in JIRA.
Group	This states that all users that belong to the specified group.
Project Role	This states that all users that belong to the specified project role.
Single Email	This states any e-mail address.

Address	
All Watchers	This states that all users that are watching this issue.
User Custom Field Value	This states that the users specified in the user-type custom field. For example, if you have a User Picker custom field called Recipient, the user selected in the custom field will receive notifications if he/she has access to the issue.
Group Custom Field Value	This states that all users that belong to the group in the group-type custom field. For example, if you have a Group Picker custom field called Approvers, all users from the group (with access to the issue) selected in the custom field will receive notifications.

As you can see, the list includes a wide range of options from issue reporters to values contained in custom fields. Basically, anything that can be represented as a user in JIRA can have notifications set up.

If a user belongs to more than one notification for a single event, JIRA will make sure that only one e-mail will be sent so the user does not receive duplicates. In order for a user to receive notifications, the user must have permission to view the issue. The only exception to this is when using the **Single Email Address** option (we will discuss security in [Chapter 9, Securing JIRA](#)). If the user does not have permission to view the issue, JIRA will not send a notification e-mail.

We will look at how you can add notifications to events so that users can start receiving e-mails; however, before that, you need to first take a look at the notification scheme.

The notification scheme

The notification scheme is a reusable entity that links events with notifications. In other words, it contains the associations between events and their respective e-mail recipients:

1. Browse to the JIRA administration console.
2. Select the **Issues** tab and then the **Notification schemes** option. This will bring up the **Notification Schemes** page:

Notification Schemes		
The table below shows the notification schemes currently configured for this server		
Name	Projects	Operations
Default Notification Scheme	<ul style="list-style-type: none">• Human Resource	Notifications · Copy · Edit · Delete
Demo Notification Scheme	<ul style="list-style-type: none">• Demonstration Project	Notifications · Copy · Edit · Delete
Help Desk Notification Scheme	<ul style="list-style-type: none">• Help Desk	Notifications · Copy · Edit · Delete
Add Notification Scheme		

From this screen, you can see a list of all the notification schemes and the projects that are currently using them.

JIRA comes with a generic default notification scheme. The default scheme is set up with notifications set for all the system events. This allows you to quickly enable notifications in JIRA. The default setup has the following notifications:

- **Current Assignee**
- **Reporter**
- **All Watchers**

You can modify the default notification scheme to add your own notification rules, but as you grow your JIRA adoption, it is a better idea to create a new scheme from scratch or copy the default scheme and make your modifications.

Adding a notification scheme

Unlike other schemes such as the workflow scheme, where JIRA will create one whenever a new project is created, all new projects will be set to use the **Default Notification Scheme**. So, if you want to create notifications specific to your project, you will have to create a new notification scheme. Perform the following steps to create a new notification scheme:

1. Browse to the **Notification Schemes** page.
2. Click on the **Add Notification Scheme** button at the bottom.
3. Enter a name and description for the new notification scheme.
4. Click on the **Add** button to create the notification scheme.

When you create a new notification scheme, you create a blank scheme that can be configured later to add your own notification rules in. It is important that you configure its notification rules before applying the scheme to projects after you create a new notification scheme; otherwise, no notifications will be sent out. We will look at how to configure notification rules later in this chapter.

Deleting a notification scheme

Unlike most other schemes, such as workflow, JIRA allows you to delete notification schemes even when they are being used by projects. However, JIRA does prompt you with a warning when you attempt to delete a notification scheme that is in use.

Perform the following steps to delete a notification scheme:

1. Browse to the **Notification Schemes** page.
2. Click on the **Delete** link for the notification scheme you wish to remove.
3. Click on the **Delete** button to remove the notification scheme.

Once you delete a notification scheme, the projects that were previously using the scheme will have no notification schemes, so you will have to reapply schemes individually. When you delete a notification scheme, you remove all the notifications you set up in the scheme.

Managing a notification scheme

Notification schemes contain notifications that are set on events in JIRA. Perform the following steps to configure a notification scheme:

1. Browse to the **Notification Schemes** page.
2. Click on the **Notifications** link for the notification scheme you wish to configure. This will bring you to the **Edit Notifications** page.

This page lists all the existing events in JIRA and their corresponding notification recipients. If you configure a new notification scheme, there will be no notifications set for the events.

Adding a notification

There are two ways you can add a new notification. You can add a notification for a specific event or you can add a notification for multiple events. Perform the following steps to add a new notification:

1. Browse to the **Edit Notifications** page for the notification scheme you wish to configure.
2. Click on the **Add notification** link or the **Add** link for the event you wish to add a notification for. Both actions will bring you to the **Add Notification** page. If you click on the **Add** link, the **Events** selection list will preselect the event for you.
3. Select the events you want to add the notification type too.
4. Select the notification type from the available options.
5. Click on the **Add** button. For example, the following screenshot shows setting up a notification for JIRA to send out e-mails to the project lead when issues are created and updated:

Add Notification

Notification Scheme: **Default Notification Scheme**

Please select the type of Notification you wish to add to scheme:

Events

- Issue Created
- Issue Updated
- Issue Assigned
- Issue Resolved
- Issue Closed
- Issue Commented
- Issue Comment Edited

(Select the notifications that you want to assign)

Group

Project Role

Single Email Address

Start typing to get a list of possible matches.

Choose a group

Choose a project role

Notifications will be sent **only** for public issues. Public issues are issues which have a Permission scheme that gives the 'Browse Projects' permission to 'Anyone'(any non-logged-in users).

All Watchers

User Custom Field Value

Choose a custom field

Group Custom Field Value

Choose a custom field

Add

Cancel

Once added, the notification will be listed against the events selected. You can continue adding notifications for the events by repeating the same steps.

Tip

You can select multiple events to add a notification type to.

Deleting a notification

When notifications are no longer required for certain events, you can also have them removed. To remove notifications, you will need to do it one by one, per event:

1. Browse to the **Edit Notifications** page for the notification scheme you wish to configure.

2. Click on the **Delete** link for the notification you wish to remove.
3. Click on the **Delete** button to remove the notification for the event.

After you remove a notification, users affected by that notification would stop receiving e-mails from JIRA. However, you need to pay attention to your configurations, as there may be other notifications for the same event that will continue to send e-mails to the same user. For example, if you created two notifications for the **Issue Created** event—one set to a **Single User** John (who belongs to the **jira-administrator** group) and another set to **jira-administrator** group—and your goal is to prevent e-mails being sent to the user John, you will need to remove both notifications from the event instead of simply the **Single User** option.

Assigning a notification scheme

When new projects are created, they are automatically assigned to use the default notification scheme. If you want your project to use a different scheme, you will need to go to the **Notifications** section of your project's administration console:

1. Browse to the project administration page for the project you want to apply the notification scheme too.
2. Select the **Notifications** option from the left panel:

The screenshot shows the 'Notifications' section of a JIRA project administration page. At the top, there is a 'Notification Helper' button and an 'Actions' dropdown menu with options 'Edit notifications' and 'Use a different scheme' (the latter is highlighted in blue). Below this, a text area explains that JIRA can notify appropriate people of particular events in the project, such as 'Issue Created', by choosing specific people, groups, or roles. A list of email addresses is provided: support@appfusions.com (with a pencil icon). The main table lists events and their associated notifications:

Events	Notifications
Issue Created	All Watchers Current Assignee Reporter
Issue Updated	All Watchers Current Assignee Reporter

3. Select **Use a different scheme** from the **Actions** menu.
4. Select the notification scheme to use.
5. Click on the **Associate** button.

As soon as a notification scheme is applied to the project, it will take effect immediately, and you will see e-mails being sent out for the events that have been configured in the scheme. Like any other schemes in JIRA, notification schemes can be assigned to multiple projects to share the same notification behavior.

Troubleshooting notifications

Often, when people do not receive notifications from JIRA, it can be difficult and frustrating to find the cause. The two most common causes for notification-related problems are either outgoing mail server connectivity or misconfiguration of the notification scheme.

Troubleshooting outgoing mail server problems is quite simple. All you have to do is try to send out a test e-mail as described in the *Sending a test mail* section. If you receive your test e-mail, then there will be no problems with your outgoing mail server configuration and you can focus on your notification configurations.

Troubleshooting notifications are not as straightforward, since there are a number of things that you will need to consider. To help with this challenge, JIRA 5 has introduced a new feature called **Notification Helper**. The notification helper can save the JIRA administrators time by helping them to pinpoint why a given user does or does not receive notifications.

All the administrator has to do is tell the helper who the user is, which issue (or an example issue from a project) the user will or will not be receiving notifications for, and the event that is triggering the notification:

1. Browse to the JIRA administration console.
2. Select the **System** tab and then the **Notification helper** option.
3. Specify the user that will or will not receive notifications in the **User** field.
4. Specify the issue to test with.
5. Select the type of notification event.
6. Click on **Submit**.

The **Notification Helper** feature will then process the input and report if the user is expected to receiving notifications, and why, based on notification scheme settings:

Notification helper

Find out why users receive, or do not receive notifications for this issue

User

Patrick Li

Event: Issue Updated

User: Patrick Li

Project: Demonstration Project

Scheme: Demo Notification Scheme

Issue: DEMO-2

Status: ✖ Patrick Li does not receive notifications for the 'Issue Updated' event

Status

Summary

Details

Current Assignee

Patrick Li is not the current assignee

Submit

As you can see from the preceding screenshot, the user, **Patrick Li**, is currently not receiving notifications for the **DEMO-2** issue when it is updated because the notification is set up to have only the **Current Assignee** receive e-mails, and **Patrick Li** is not the assignee.

Incoming e-mails

We have seen how you can configure JIRA to send e-mails to notify users about updates on their issues. Although, this is only half of the story when it comes to JIRA's e-mail support.

You can also set up JIRA for it to periodically poll mailboxes for e-mails and create issues based on the e-mails' subject and content. This is a very powerful feature with the following benefits:

- It hides the complexity of JIRA from business users, so they can log issues more efficiently and leave the complexity to the IT team
- It allows users to create issues even if JIRA can only be accessed within the internal network. Users can send e-mails to a dedicated mailbox for JIRA to poll

Adding an incoming mail server

For JIRA to retrieve e-mails and create issues from them, you need to add the POP/IMAP mail server configurations to JIRA. POP and IMAP are mail protocols used to retrieve e-mails from the server. E-mail clients, such as Microsoft Outlook, use one of these protocols to retrieve your e-mails.

Unlike outgoing mail servers, JIRA allows you to add multiple incoming mail servers. This is because while you only need one mail server to send e-mails, you may have multiple mail servers or multiple mail accounts (on the same server) that people will use to send e-mails to. For example, you might have one dedicated to provide support and another one for sales. It is usually a good idea to create separate mail accounts to make it easier when trying to work out which e-mail can go into which project. For this reason, adding POP/IMAP mail servers can be thought of as adding multiple mail accounts in JIRA. Perform the following steps to add an incoming mail server:

1. Browse to the JIRA administration console.
2. Select the **System** tab and then the **Incoming Mail** option.
3. Click on the **Add POP/IMAP mail server** button.
4. Enter a name and description for the mail server.
5. Select the type of mail service provider. For example, if you are using your own hosted mail service or one of the recognized cloud provider such as Google.
6. Specify the host name of the POP/IMAP server if you are using your own (custom provider).
7. Enter the username/password credentials for the mail account.
8. Click on the **Add** button to create the POP/IMAP mail server:

Add POP / IMAP Mail Server

Use this page to add a new POP / IMAP server for JIRA to retrieve mail from.

Name *

The name of this server within JIRA.

Description

Service Provider Custom

Protocol POP

Host Name *

The host name of your POP / IMAP server.

POP / IMAP Port

Optional - The port to use to retrieve mail from your POP / IMAP account. Leave blank for default. (defaults: POP - 110, SECURE_POP - 995, IMAP - 143, SECURE_IMAP - 993)

Timeout 10000

Timeout in milliseconds - 0 or negative values indicate infinite timeout. Leave blank for default (10000 ms).

Username *

The username used to authenticate your POP / IMAP account.

Password *

The password for your POP / IMAP account.

Test Connection

Add

Cancel

Note

You can have multiple incoming servers.

Mail handlers

Mail handlers are what JIRA uses to process retrieved e-mails. Each mail handler is able to process e-mails from one incoming mail server and periodically scan for new e-mails.

JIRA ships with a number of mail handlers, each with their own features. In the following sections, we will discuss each of the handlers in detail.

Creating a new issue or adding a comment to an existing issue

Creating a new issue or adding a comment to an existing issue mail handler (also known as the **Create** and **Comment Handler** in previous versions of JIRA) is the most used mail handler. It will create new issues from the received e-mails and also add comments to existing issues if the incoming e-mail's subject contains a matching issue key. If the subject does not contain a matching issue key, a new issue is created. The following table lists the parameters required when creating the mail handler:

Parameter	Description
Project	This is the project in which issues will be created. This is not used for commenting where the e-mail subject will contain the issue key.
Issue Type	This is the issue type for newly created issues.
Strip Quotes	If this is present in the parameters, quoted text from the e-mail will not be added as a part of the comment.
Catch E-mail Address	This specifies if JIRA is to only handle e-mails that are sent to the specified address.
Bulk	<p>This specifies how to handle autogenerated e-mails such as those generated by JIRA. It is possible to create a loop if JIRA sends e-mails to the same mailbox where it also picks up e-mails. In order to prevent this, you can specify one of the following:</p> <ul style="list-style-type: none">• ignore: This is used to ignore these e-mails• forward: This is used to forward these e-mails to another address• delete: This is used to delete these e-mails altogether <p>Generally, you can set it to forward.</p>

Forward Email	If this is specified, then the mail handler is unable to process an e-mail message it receives. An e-mail message indicating this problem will be forwarded to the e-mail address specified in this field.
Create Users	If the e-mail is sent from an unknown address, JIRA will create a new user based on the e-mail "from" address and randomly generate a password. An e-mail will be sent to the "from" address informing the new JIRA account user.
Default Reporter	This specifies the username of a default reporter, which will be used if the e-mail address in the From field of any of the received messages does not match the address associated with that of an existing JIRA user.
Notify Users	Uncheck this option if you do not want JIRA to notify new users created as per the Create Users parameter .
CC Assignee	JIRA will assign the issue to the user specified in the To field first. If no user can be matched from the To field, JIRA will then try the users in the CC and then BCC list.
CC Watchers	JIRA will add users in the CC list (if they exist) as watchers of the issue.

Adding a comment with the entire e-mail body

This mail handler extracts text from an e-mail's content and adds it to the issue with a matching issue key in the subject. The author of the comment is taken from the **From** field.

It has a set of parameters similar to the **Create and Comment handler**.

Adding a comment from the non-quoted e-mail body

Adding a comment from the non-quoted e-mail body is very similar to the **Full Comment** handler, but it only extracts non-quoted texts and adds them as comments. Texts that start with > or | are considered to be quoted.

It has a set of parameters similar to the **Create and Comment handler**.

Creating a new issue from each e-mail message

Creating a new issue from each e-mail message is quite similar to the **Create and Comment handler**, except this will always create a new issue for every received e-mail.

It has a set of parameters similar to the **Create and Comment handler**.

Adding a comment before a specified marker or separator in the e-mail body

Adding a comment before a specified marker or separator in the e-mail body is a more powerful version of the comment handlers. It uses regular expressions to extract texts from e-mail contents and adds them to the issue:

Parameter	Description
Split Regex	<p>This regex expression is used to extract contents. There are two rules for the regex expression:</p> <ul style="list-style-type: none">• It must start and end with a delimiter character, usually with /• It cannot contain commas, for example, / - {} {} {} {} {} \s*Original Message\s* {} - / or / _____ * /

Adding a mail handler

You can set up as many mail handlers as you want. It is recommended that you create dedicated mailboxes for each project you wish to allow JIRA to create issues from e-mails. For each account, you will then need to create a mail handler. The mailbox you set up needs to be accessible through POP or IMAP.

Perform the following steps to add a mail handler:

1. Browse to the **Incoming Mail** page.
2. Click on the **Add incoming mail handler** button.
3. Provide a name to the new mail handler.
4. Select an incoming mail server or **Local Files**.
5. Specify how long JIRA can wait to poll the mailbox for new e-mails (in minutes). You will want to keep this long enough to allow enough time for JIRA to process all the e-mails, but not too long as you may end up having to wait for a long time to see your e-mails converted into issues in JIRA.
6. Select the type of handler you want to add.
7. Click on the **Next** button:

The screenshot shows a configuration dialog box titled "Mail Handler". It contains the following fields:

- Name ***: HD: Create and comment mail handler
- Server**: Gmail
- Delay**: 1
Delay between running time, in minutes.
- Handler**: Create a new issue or add a comment

At the bottom right of the dialog are "Next" and "Cancel" buttons.

Depending on the handler type you select, the next screen will vary. On the next screen, you will need to provide the required parameters for the mail handler, as described in the preceding section. The following screenshot shows an example configuration dialog box, where new issues will be created in the **Help Desk** project as **Task**:

Create a new issue or add a comment to an existing issue

Project 

Default project where new issues are created.

Issue Type 

Default type for new issues.

Strip Quotes

If checked quoted text is removed from comments.

Catch Email
Address

If set, only emails having the specified recipient in fields To, Cc or Bcc will be processed.

Bulk 

Action that will be performed for emails with the 'Precedence: bulk' or emails with an 'Auto-Submitted' header that is not set to "no".

Forward Email

Create Users

If a message comes from an unrecognised address, create a new JIRA user with the user name and email address set to the 'From' address of the message.

The password for the new user is randomly generated, and an email is sent to the new user informing them about

Tip

You can always use the **Test** button to test out your configuration. JIRA provides helpful hints if there are problems.

Editing and deleting a mail handler

You can update the details of your mail handlers at any time. You will often need to tune your handler parameters a few times until you get your desired results. Perform the following steps to update a mail handler:

1. Browse to the **Incoming Mail** page.
2. Click on the **Edit** link for the mail handler you wish to update.
3. Update the configure options.

Once updated, the changes will be applied immediately and JIRA will use the new handler parameters for the next polling run.

You can also delete mail handlers that are no longer required at any time. Perform the following steps to delete a mail handler:

1. Browse to the **Incoming Mail** page.
2. Click on the **Delete** link for the mail handler you wish to remove.

Note

You will not be prompted with a confirmation page. The mail handler will be removed immediately, so think carefully before you delete it.

Advanced mail handler

The default mail handlers that come with JIRA are often enough for simple e-mail processing needs. If you need to have more control or need special processing logics for your incoming e-mails, you can create custom mail handlers. However, creating new mail handlers requires you to have a knowledge of programming; a better option is to use an add-on called **Enterprise Mail Handler (JEMH)** for JIRA.

With JEMH, you can set up advanced e-mail routing, additional e-mail triggered operations such as updating an issue based on your e-mail content, audit of received/processed e-mails, and more. You can find more about JEMH at

<https://marketplace.atlassian.com/plugins/com.jawaholic.jira.jemh-ui/server/overview>.

The HR project

Users will often want to get progress updates on their issues after they have logged them. So, instead of business users having to ask for updates, we will proactively update them through our newly acquired knowledge, that is, JIRA notifications.

In [Chapter 5, Field Management](#), we added a custom field called **Direct Manager**, which allows users to add the manager of the new employee or leaving employee, so she can be kept in the loop.

The other customization we made in [Chapter 7, Workflow and Business Process](#), is the addition of new transitions in the workflow. We need to make sure that those transitions fire appropriate events and also send out notifications. In summary, we need to do the following:

- Send out notifications for the events fired by our custom workflow transitions
- Send out notifications to users specified in our **Direct Manager** custom field

While you can achieve both using other JIRA features, such as adding users as watchers to the issue and reusing existing JIRA system events, this exercise will explore the options available to you. In later chapters, you will see there are other criteria to consider while deciding on the best approach.

Setting up mail servers

The first step to enable e-mail communication, as you will have guessed, is to register mail servers in JIRA. If you are using the standalone distribution of JIRA, it is recommended that you add your mail server by entering the host information:

1. Log in to JIRA as a JIRA administrator.
2. Browse to the JIRA administration console.
3. Select the **System** tab and then the **Outgoing Mail** option.
4. Click on the **Configure new SMTP mail server** button.
5. Enter your mail server information. If you do not have a mail server handy, you can sign up for a free Gmail account and use that for testing purposes.

After adding your mail server, you can try sending yourself a quick test e-mail to check whether JIRA is able to access your server successfully.

Updating workflow post functions

In [Chapter 7](#), *Workflow and Business Process*, we created a few new workflow transitions. We now need to update these new transitions to make sure they fire appropriate events.

1. Browse to the **View Workflows** page.
2. Click on the **Edit** link for HR: Termination Workflow.
3. Click on any transitions other than **Done**.
4. Update the post function to fire the `Issue Updated` event rather than the `Generic Event`.
5. Repeat this for all other transitions except the **Done** transition.
6. Publish the draft workflow. You can save a backup copy in case you want to revert.

We are using the **Issue Updated** event because it reflects the fact that the issue is being updated; also, the event is tied to more appropriate e-mail templates. We can of course, also create new custom event and e-mail templates and make the post function to fire the custom event instead.

Setting up a notification scheme

Now, you need to have your own notification scheme, so you can start adding notifications to your events. We will base our notification scheme on the default scheme to help us get things set up quickly:

1. Select the **Issues** tab and then the **Notification schemes** option.
2. Click on the **Copy** link for **Default Notification Scheme**.
3. Click on the **Edit** link of the copied notification scheme.
4. Rename it **HR Notification Scheme** and click on **Update**.

This will create a new notification scheme with the basic notifications prepopulated. All you need to do now is modify the events and add your own notification needs.

Setting up notifications

There are two rules you need to follow to add notifications. First, you need to add notifications for your custom events so that e-mails will be sent out when they are fired. Second, you will want users specified in the CC list custom field to also receive e-mails along with the assignee and reporter of the issue:

1. Click on the **Notifications** link for HR Notification Scheme.
2. Click on the **Add notification** link.
3. Select the Issue Updated event type.
4. Select **User Custom Field Value** for the notification type and select Direct Manager from the drop-down list.
5. Click on the **Add** button.

Nice and easy. With just a few clicks, you have added the **Direct Manager** custom field to the notification scheme. So now, regardless who is put into the field, the user will receive notifications for issue updates.

Putting it together

The last step, as always, is to associate your scheme with projects for activation:

1. Browse to the HR project's administration page.
2. Select the **Notifications** option from the left panel.
3. Select **Use a different scheme** in the **Actions** menu.
4. Select the new **HR Notification Scheme** we just created.
5. Click on the **Associate** button.

With just a few clicks, you enable JIRA to automatically send out e-mails to update users with their issue's progress. Not only this, but you have tied in the custom fields you created from earlier chapters to manage who, along with the issue assignee and reporter, will also get these notifications. So let's put this to the test!

1. Create a new **Termination** issue in the HR project.
2. Select a user for the **Direct Manager** custom field. It is a good idea not to select yourself since the reporter will get notifications by default. Also, make sure that the user selected has a valid e-mail address.
3. Transition the issue to move along the workflow.
4. You will receive e-mails from JIRA within minutes.

If you do not receive e-mails from JIRA, check your mail queue and check whether the mail is being generated and follow the steps from the *Troubleshooting notifications* section in this chapter.

Summary

In this chapter, we looked at how JIRA can stay in touch with its users through e-mails. Indeed, with today's new gadgets, such as smartphones and tablets, being able to keep users updated with e-mails is a powerful feature, and JIRA has a very flexible structure in place to define the rules on who will receive notifications.

We also very briefly mentioned some of the security rules about who can receive notifications. JIRA performs security checks prior to sending out notifications for two very good reasons: first, there is no point sending out an e-mail to a user who cannot view the issue; second, you will not want unauthorized users to view the issue and receive updates that they will not know about.

In the next chapter, we will look into the security aspects of JIRA and how you can secure your data to prevent unauthorized access.

Chapter 9. Securing JIRA

In the previous chapters, you learned how to store data in JIRA by creating issues. As you can see, as an information system, JIRA, is all about data. It should come as no surprise to you that security plays a big role in JIRA, not only to ensure that the right people will get access to our data, but also to maintain data integrity by preventing accidental changes.

By the end of this chapter, you will have learned the following:

- User directories and how to connect JIRA to LDAP
- General access control in JIRA
- Managing fine-grained permission settings
- How to troubleshoot permission problems

Before we delve into the deep end of how JIRA handles security, let's first take a look at how JIRA maintains user and group memberships.

User directories

User directories are what JIRA uses to store information about users and groups. A user directory is backed by a user repository system, such as LDAP, a database, or a remote user management system, such as Atlassian Crowd.

You can have multiple user directories in JIRA. This allows you to connect your JIRA instance to multiple user repositories. For example, you can have an LDAP directory for your internal users and a database directory (a JIRA internal directory) for external users. An example is given in the following screenshot, where we have two user directories configured. The first user directory is the built-in JIRA **Internal** directory running on the JIRA database. The second user directory is connected to the **Microsoft Active Directory (Read Only)** in the read-only mode. The last user directory is connected to the crowd, a user identity management software from Atlassian:

User Directories 

The table below shows the user directories currently configured for JIRA.

The order of the directories is the order in which they will be searched for users and groups. Changes to users and groups will be made in the first directory where JIRA has permission to make changes. It is recommended that each user exist only in a single directory.

Directory Name	Type	Order	Operations
JIRA Internal Directory You cannot edit this directory because you are logged in through it, please log in as a locally authenticating user to edit it.	Internal	↓	Edit
Active Directory server	Microsoft Active Directory (Read Only)	↑ ↓	Disable Edit Test Synchronise Never synchronised.
Crowd Server	Atlassian Crowd	↑	Disable Edit Test Synchronise Never synchronised.

[Add Directory](#)

Additional Configuration & Troubleshooting

- [Directory Configuration Summary](#)

As a JIRA administrator, you can manage user directories by performing these two steps:

1. Browse to the JIRA administration console.
2. Select the **User management** tab and then the **User Directories** option.

From here, you can see the list of user directories you currently have configured in JIRA, add new directories, and manually synchronize with the remote user repository.

When adding a new user directory, you need to first decide on the directory type. There are several different user directory types within JIRA:

- **JIRA internal directory:** This is the built-in default user directory when you first install JIRA. With this directory, all the user and group information is stored in the JIRA database.
- **Active directory (AD)/LDAP:** This is used when you want to connect JIRA to an LDAP server. With this directory, JIRA will use the backend LDAP to query user information and group membership. This is also known as an **LDAP connector** and should not be confused with internal and LDAP authentication directories.
- **Internal with LDAP authentication:** This is also known as a **Delegated LDAP**. With this directory type, JIRA will only use LDAP for authentication and will keep all user information internally in the database (retrieved from LDAP when the user successfully authenticates for the first time). This approach can give a better performance. Since LDAP is only used for authentication, this avoids the need to download larger numbers of groups from LDAP.
- **Atlassian Crowd:** If you are also using Atlassian Crowd, a user management and **Single Sign-On (SSO)** solution, you can use this directory type to connect to your crowd instance. With this option, you can also configure your JIRA instance to participate in the SSO session.
- **Atlassian JIRA:** JIRA is capable of acting as a user repository for other compatible applications. If you have another JIRA instance running, you can use this directory type to connect to the other JIRA instance and for user information.

When you have multiple user directories configured for JIRA, there are a few important points to keep in mind. The order of the user directories is important, as it will directly affect the order JIRA will use to search users and apply changes made to users and groups. For example, if you have two user directories and both have a user called **admin** with different passwords, this will have the following effects:

- When you log in to JIRA with the user admin, you will be logged in as the admin user from the first user directory that is able to validate the password, in the order of listed directories.
- After logging in, you will be granted group membership from the directory that has validated your password. Any other directories will be skipped.
- If you make a change to the admin user, such as changing the full name, then the changes will only be applied to the first directory JIRA has write access to.

Another important point to remember when working with user directories is that you cannot make changes to the user directory when you are logged in with a user account that belongs to the said directory. For example, if you are logged in with an LDAP account, then you will not be able to make changes to JIRA's LDAP settings, since there is a potential for the new change to actually lock you out of JIRA.

Tip

Always have an active administrator user account ready in the default JIRA internal directory; for example, the account created during the initial setup. This will provide you with an administrator account that can help you fix user directory problems such as the preceding scenario. If you have a user account with the same name in the other user directory, then the internal directory should also be the first one in the list.

Connecting to LDAP

JIRA supports a wide range of LDAP servers including Microsoft Active Directory, OpenLDAP, and Novell eDirectory server. If a particular LDAP is not listed as one of the options, then we also have a **Generic Directory Server** option.

When using the AD/LDAP connector directory type, you can choose to connect with one of the permission options:

- **Read only:** JIRA cannot make any modifications to the LDAP server.
- **Read only, with local groups:** Information retrieved from LDAP will be read-only, but you can also add users to groups created within JIRA. These changes will not be reflected in LDAP.
- **Read/Write:** JIRA will be able to retrieve and make changes to the LDAP server.

The **Read only** option is the most common option, as the IT team often centrally manages LDAP servers and changes are not allowed. With this option, JIRA will only use data stored in LDAP to verify user credentials and group membership. If you only want to use LDAP as a user repository and authentication, but still want to have the flexibility to update group membership without having to get the LDAP team involved, then the **Read only, with local groups** option will be the best fit. Lastly, the **Read/Write** option should be avoided, as propagating changes to LDAP, such as group membership, can have an unforeseen impact on other systems also relying on the same LDAP server.

To connect your JIRA to LDAP, all you have to do is add a new user directory:

1. Browse to the **User Directories** page.
2. Click on the **Add Directory** button and select either **Microsoft Active Directory** or **LDAP** from the **Directory Type** select list, and then click on **Next**.
3. Provide your LDAP server information.

Since every LDAP is different, the exact parameters that are required will vary. At a minimum, you need to provide the following information:

Parameter	Description
Name	This is the name of the user directory.
Directory Type	This is where you select the flavor of your LDAP. This will help JIRA to prefill some of the parameters for you.
Hostname	This is the hostname of your LDAP server.

Port	This is the port number of your LDAP server. JIRA will prefill this based on your directory type selection.
Base DN	This is the root node for JIRA to search for users and groups.
LDAP Permissions	This helps choose whether JIRA should be able to make changes to LDAP.
Username	This is the username that JIRA will use to connect to LDAP for user and group information.
Password	This is the password that JIRA will use to connect to LDAP.

You can see these sections completed in the following screenshot:

Configure LDAP User Directory [?](#)

The settings below configure an LDAP directory which will be regularly synchronised with JIRA. Contact your server administrator to find out the required settings for your LDAP server.

Server Settings

Name: [?](#)

Directory Type:

Hostname:
Hostname of the server running LDAP. Example: ldap.example.com

Port: Use SSL

Username:
User to log in to LDAP. Examples: user@domain.name or cn=user,dc=domain,dc=name.

Password:

LDAP Schema

Base DN:
Root node in LDAP from which to search for users and groups. Example: cn=users,dc=example,dc=com.

Additional User DN:
Prepended to the base DN to limit the scope when searching for users.

Additional Group DN:
Prepended to the base DN to limit the scope when searching for groups.

LDAP Permissions

Read Only

Users, groups and memberships are retrieved from your LDAP server and cannot be modified in JIRA.

Read Only, with Local Groups

Users, groups and memberships are retrieved from your LDAP server and cannot be modified in JIRA. Users from LDAP can be added to groups maintained in JIRA's internal directory.

Read/Write

Modifying users, groups and memberships in JIRA will cause the changes to be applied directly to your LDAP server. Your configured LDAP user will need to have modification permissions on your LDAP server.

Apart from the preceding parameters, there are additional advanced settings such as **User Schema Settings** and **Group Schema Settings**. After filling in the form, you can click on the **Quick Test** button to verify that JIRA is able to connect to your LDAP server and authenticate with the username and password provided. Note that this does not test for things such as the user lookup. If the initial quick test is successful, then you can go ahead and click on the **Save and Test** button. This will add the user directory and take you to the test page where you can test the settings with a proper user credential (this will be different than the one used by JIRA to connect to LDAP):

Test Remote Directory Connection

Use this form to test the connection to Microsoft Active Directory (Read Only) directory 'Active Directory server'.

For extended testing enter the credentials of a user in the remote directory.

User name

patrick

Password

Test basic connection : Succeeded

Test retrieve user : Succeeded

Test get user's memberships with 2 groups retrieved. : Succeeded

Test retrieve group : Succeeded

Test get group members with 2 users retrieved. : Succeeded

Test user can authenticate : Succeeded

[Test Settings](#)

[Edit Settings](#)

[Back to directory list](#)

After the new user directory is added, JIRA will automatically synchronize with the LDAP server and pull in users and groups. Depending on the size of your LDAP server, this may take some time to complete. After the initial synchronization, JIRA will periodically synchronize with LDAP for any changes.

Users

In JIRA, each user needs to have an account for them to access JIRA, unless JIRA is configured to allow anonymous access (by selecting the **Anyone** group in the **Browse Project** permission scheme; refer to the *Permission schemes* section in this chapter for details). Each user is identified by their username. In JIRA 7, usernames can be changed after the account is created.

User browser

The user browser is where you will be able to see a list of all the users in JIRA, including their usernames, e-mail addresses, last login attempt, and which user directory they belong to. User browser also provides you with search capabilities. You will be able to search for users that fit in the criteria such as username, full name, e-mail address, and group association. Perform the following steps to access the user browser:

1. Browse to the JIRA administration console.
2. Select the **User management** tab and then the **Users** option. This will bring up the **User Browser** page.

By default, the results will be paginated to show 20 users per page, but you can change this setting to show up to 100 users per page. When dealing with large deployments having hundreds of users, these options will become very useful to quickly find the users you need to manage.

Other than providing the ability for you to effectively search for users, the user browser also serves as the portal for you to add new users to JIRA and manage a user's group/role associations:

Users							Invite users	Create user
Filter users		In group	Application access	Users per page				
Name, username or email		Any	All Users	20	Filter	Reset filter		
Displaying users 1 to 4 of 4.								
Full name	Username	Login details	Group name	Applications	Directory			
 John Stein	john john@test.com	Count: 1 Last: 24/Aug/16 6:10 PM	jira-software-users	JIRA Software	JIRA Internal Directory	Edit	...	
 John Doe	john.doe john.doe@test.com	Count: 1 Last: 12/Sep/16 6:05 PM	jira-software-users	JIRA Software	JIRA Internal Directory	Edit	...	
 Kim Lee	kim dragonite40@hotmail.com	Count: 1 Last: 24/Aug/16 6:10 PM	jira-software-users	JIRA Software	JIRA Internal Directory	Edit	...	
 Patrick Li	patrick patrick@appfusions.com	Count: 56 Last: Today 12:29 PM	jira-administrators jira-software-users	JIRA Software	JIRA Internal Directory	Edit	...	

Adding a user

New users can be added to JIRA in a number of ways:

- Direct creation by the JIRA administrator
- Invitation by the JIRA administrator to create an account
- By signing up for an account if the public signup option is enabled
- Synchronization of user accounts from an external user repository such as LDAP

The first and second options have centralized management, where only the JIRA administrators can create and maintain user accounts. This option is applicable to the most private JIRA instances designed to be used by an organization's internal users.

The third option allows users to sign up for accounts by themselves. This is most useful when you run a public JIRA instance, where manually creating user accounts is not scalable enough to handle the volume. We will be looking at how to enable public signup options in later sections in this chapter. For now, we will examine how administrators can create user accounts manually:

1. Browse to the **User Browser** page.
2. Click on the **Create user** button.
3. Enter a unique username for the new user. JIRA will let you know if the username is already taken.
4. Enter the password, full name, and e-mail address for the user. If you do not enter a password, a random password will be generated. In this case, you should select the **Send notification email** option so that the new user can reset their password.
5. Select what applications in JIRA the new user will have access to. For example, if you are running JIRA Software, you should check the JIRA Software option. Doing so will consume one license seat count.
6. Click on the **Create user** button to create the new user.

Alternatively, the administrator can also choose to invite users so that they can create their accounts themselves. This is different than the public signup option, since only recipients of the invitations will be able to create accounts. For this feature to work, you will need to have an outgoing mail server configured, as the invitations will be sent as e-mails. Perform the following steps to invite users to sign up:

1. Browse to the **User Browser** page.
2. Click on the **Invite users** button.
3. Specify the e-mail addresses for the people you wish to invite. You can invite multiple people at once.
4. Click on the **Invite users** button to send out the invitations.

Enabling public signup

If your JIRA is public (for example, an open source project), then creating user accounts individually as explained earlier will become a very demanding job for your administrator. For this type of JIRA setup, you can enable public signup to allow users to create accounts by themselves. Perform the following steps to enable public signup in JIRA:

1. Browse to the JIRA administration console.
2. Select the **System** tab and then the **General configuration** option.
3. Click on the **Edit Settings** button.
4. Select **Public** for the **Mode** field.
5. Click on the **Update** button to apply the setting.

Once you have set JIRA to run in the **Public** mode, users will be able to sign up and create their own accounts from the login page:

The screenshot shows a JIRA login interface. At the top, there is a blue header bar with the word "Login". Below it, there are two input fields: "Username" and "Password". Underneath these fields is a checkbox labeled "Remember my login on this computer". To the right of the checkbox is a link "Not a member? Sign up for an account." This link is highlighted with a red rectangular border. At the bottom of the form, there are two buttons: "Log In" and "Can't access your account?".

As you will see in the *Global permissions* section later in this chapter, once a user signs up for a new account, they will automatically join groups with JIRA users' global permission. If you have set JIRA to run in the **Private** mode, then only the administrator will be able to create new accounts.

Enabling CAPTCHA

If you're running JIRA in the **Public** mode, you run the risk of having automated spam bots creating user accounts on your system. To counter this, JIRA provides the CAPTCHA service, where potential users will be required to type a word represented in an image into a text field. Perform the following steps to enable the CAPTCHA service:

1. Browse to the JIRA administration console.
2. Select **System** tab and then the **General configuration** option.
3. Click on the **Edit Settings** button.
4. Select **On** for the **CAPTCHA on signup** field.
5. Click on the **Update** button to apply the setting.

Now, when someone tries to sign up for an account, JIRA will present them with a CAPTCHA challenge that must be verified before the account is created:

The screenshot shows a 'Sign up' form with four input fields: Email, Full name, Username, and Password. Below these is a CAPTCHA challenge: a text input field labeled 'Please enter the word as shown below' followed by a distorted blue text 'chesper'. At the bottom are 'Sign up' and 'Cancel' buttons.

Sign up

Email * E.g. charlie@atlassian.com

Full name * Your full name

Username * Desired username

Password * Password

Please enter the word as shown below

Groups

Groups are a common way of managing users in any information system. A group represents a collection of users, usually based on their positions and responsibilities within the organization. In JIRA, groups provide an effective way to apply configuration settings to users, such as permissions and notifications.

Groups are global in JIRA, which is something that should not be confused with project roles (which we will discuss later). This means if you belong to the `jira-administrators` group, then you will always be in that group regardless of which project you are accessing. You will see in later sections how this is different from project roles and their significance.

Group browser

Similar to user browser, the group browser allows you to search, add, and configure groups within JIRA:

1. Browse to the JIRA administration console.
2. Select the **User management** tab and then the **Groups** option. This will bring up the **Group Browser** page:

The screenshot shows the JIRA Group Browser interface. At the top right are buttons for "Bulk edit group members" and a help icon. On the left, there's a "Filter group" section with fields for "Name contains" and "Groups per page" set to 20, along with "Filter" and "Reset filter" buttons. The main area displays a table of existing groups:

Group name	Users	Permission schemes	Operations
engineering	0		Edit members · Delete
jira-administrators	1	ADMIN JIRA SOFTWARE	Edit members · Delete
jira-software-users	4	JIRA SOFTWARE	Edit members · Delete

A red box highlights the "Add group" section on the right, which contains a "Name" input field and a "Add group" button.

JIRA comes with a few default groups. These groups are created automatically when you install JIRA. For JIRA Software, we have the following:

Group	Description
jira-administrators	Administrators of JIRA. By default, this group lets you access the administration console.
jira-software-users	By default, members of this group will have access to the JIRA Software application.

Other JIRA applications, such as the JIRA Service Desk, will have different sets of default groups.

Adding a group

Other than the three groups that come by default with JIRA, you can create your own groups. It is important to note that once you create a group, you cannot change its name. Therefore, make sure that you think about the name of the group carefully before you create it:

1. Browse to the **Group Browser** page.
2. Enter a unique name of the new group in the **Add group** section.
3. Click on the **Add group** button to create the new group.

After a group is created, it will be empty and have no members; you will need to manually add users to the group.

Editing group memberships

Often, people move around within an organization, and your JIRA needs to be kept up to date with the movement. In the group browser, there are two ways to manage group memberships. The first option is to manage the membership on a per group level, and the second option is to manage several groups at the same time. Both these options are actually similar, so we will be covering both at the same time.

Perform the following steps to manage individual groups:

1. Browse to the **Group Browser** page.
2. Click on the **Edit members** link for the group you wish to manage members on. This will bring you to the **Bulk Edit Group Members** page.

Perform the following steps to manage multiple groups:

1. Browse to the **Group Browser** page.
2. Click on the **Bulk edit group members** button at the top. This will bring you to the **Bulk Edit Group Members** page.

You will notice that both options will take you to the same page. The difference is that if you have chosen the individual group option, JIRA will auto select the group to update, and if you have chosen the bulk edit option, then no groups will be selected. However, regardless of which option you choose, you can still select one or all the groups to apply your changes to:

Groups

Bulk edit group members

This page allows you to edit the user memberships for each group.

You can add to and remove users from multiple groups at a time. When selecting multiple groups please note:

- All the common users in the selected groups are displayed under the 'All' label and the remaining disparate users are displayed under the label with its group name.
- **Removing Users** - Removing user(s) listed in the 'All' section will remove the selected user(s) from all of the selected groups. However if user(s) are selected under a specific group name(s), the selected user(s) will be removed from the group its listed under.
- **Adding Users** - All user(s) to be added are added to all of the selected group(s).

Step 1: Select group(s) to edit and refresh the members list

Step 2: Select users to leave OR join the selected group(s) and click on the corresponding button

Selected 1 of 3 groups	4 Group member(s)	Add members to selected group(s)
jira-software-users ×	jira-software-users john john.doe kim patrick	<input type="text"/> Begin typing to find users. Add selected users
		Remove selected users

Perform the following steps to update the membership in one or more groups:

1. Browse to the **Bulk Edit Group Members** page.
2. Select one or more groups to update.
3. Select users from the middle box and click on the **Remove selected users** button to take users out of the groups.
4. Specify users (by typing usernames) in the right-hand side box and click on the **Add selected users** button to add users to the groups.

Deleting a group

If a group has become redundant, you can remove it from JIRA:

1. Browse to the **Group Browser** page.
2. Click on the **Delete** link for the group you wish to remove, and click on **Delete** again to permanently remove the group.

Once you remove the group, all the users who previously belonged to it will have their group associations updated to reflect the change. However, if you have other configurations using the group, it can have a negative impact if you are not careful. For example, if you are restricting the **Create Issue** project permission to only a group called developers in your permission scheme, by deleting the developers group, nobody will be able to create issues in the projects using the permission scheme.

Note

Be very careful when deleting a group, as it might be used in other configurations.

Project roles

As you have seen, groups are collections of users and are applied globally in JIRA to all projects. JIRA also offers another way of grouping users, which is applied on the project level only.

Project role browser

Similar to users and groups, project roles are maintained by the JIRA administrator through the **Project Role Browser** page. There is a slight difference, however, because since project roles are specific to projects, JIRA administrators only define what roles are available in JIRA and their default members. Each project's administrators (discussed in later sections) can further define each role's membership for their own projects, overriding the default assignment. We will first look at what JIRA administrators can control through the **Project Role Browser** page and then look at how project administrators can fine-tune the membership assignment later.

Perform the following steps to access the **Project Role Browser** page:

1. Browse to the JIRA administration console.
2. Select the **System** tab and then the **Project roles** option. This will bring up the **Project Role Browser** page:

The screenshot shows the 'Project Role Browser' page. At the top, there is a brief description: 'You can use project roles to associate users and/or groups with specific projects. The table below shows all the project roles that are available in JIRA. Use this screen to add, edit and delete project roles. You can also click 'View Usage' to see which projects, permission schemes and notification schemes are using project roles.' Below this is a table with three columns: 'Project Role Name', 'Description', and 'Operations'. The table contains one row for the 'Administrators' role. The 'Operations' column for this row includes links for 'View Usage', 'Manage Default Members', 'Edit', and 'Delete'. At the bottom of the page is a form titled 'Add Project Role' with fields for 'Name' and 'Description', and a 'Add Project Role' button.

Project Role Name	Description	Operations
Administrators	A project role that represents administrators in a project	View Usage · Manage Default Members · Edit · Delete

Add Project Role

Name

Description

Add Project Role

Adding a project role

To start creating your own project roles, you will first need to add the role as an administrator, and then each project administrator will be able to add users to it. Perform the following steps to create a new project role:

1. Browse to the **Project Role Browser** page.
2. Enter a unique name for the new project role in the **Add Project Role** section.
3. Click on the **Add Project Role** button to create the project role.

Once you add a new project role, it will appear for all the projects.

Managing default members

You can assign default members for project roles, so newly created projects will have project roles assigned to them. Default members are an efficient way for JIRA administrators to assign project role members automatically, without having to manually manage each new project as it comes in.

For example, by default, users in the `jira-administrators` group will have the **Administrators** project role. This not only increases the efficiency of the setup by creating a baseline for new projects, but also offers the flexibility to allow modifications to the default setup to cater to unique requirements.

Perform the following steps to set default members for a project role:

1. Browse to the **Project Role Browser** page.
2. Click on the **Manage Default Members** link for the project role you wish to edit.

The following screenshot shows that the **Administrators** project role has a default user (`Patrick Li`) and a default group (`jira-administrators`):

Default Users	Default Groups
Patrick Li Edit	jira-administrators Edit

On this page, you will see all the default members assigned to the selected project role. You can assign default memberships based on individual users or groups.

Perform the following steps to add a default user/group for the project role:

1. Click on the **Edit** link for the default member option (either the user or group).
2. Use the user picker/group picker function to select the users/groups you wish to assign to the project role.
3. Click on the **Add** button to assign the role. The following screenshot shows that the **jira-administrators** group is the default group for the **Administrators** project role:

Assign Default Groups to Project Role: Administrators

You can add and remove default groups from the project role **Administrators** by using the 'Join' and 'Leave' buttons below.

- [**<< Return to viewing project role Administrators**](#)

Add group(s) to project role:

Add

Groups in Project Role

jira-administrators

Remove

Once added, any new projects created will have the specified users/groups assigned to the project role. It is important to note that after you have set default members, only new projects will have the settings applied. Existing projects will not retrospectively have the default members applied.

Note

The default membership changes the project roles only to affect new projects.

Assigning project role members

As you have seen, JIRA allows you to assign default members to projects when they are created. This might be sufficient for most projects when they start, but changes will often need to be made due to staff movements throughout the project life cycle. While it is possible for the JIRA administrator to continue maintaining each project's membership, it can easily become an overwhelming task, and in most cases, since project roles are specific to each project, it makes sense to delegate this responsibility to the owner of each project.

In JIRA, an owner of a project is someone with the **Administer Projects** permission. By default, members of the administrators' project role will have this permission. We will see in a later section how to manage permissions in JIRA.

As a project administrator, you will be able to assign members to various project roles for your project. You can assign roles from the project administration page, as follows:

1. Browse to the project administration page for the project you want to update.
2. Select the **Users and roles** option from the left panel.
3. Click on the **Add users to a role** link.
4. Start typing the user's username or the group's name. JIRA will auto-search for results as you type.
5. Click on the **Add** button once you have found the user/group you want to add.

The screenshot shows the JIRA 'Users and roles' administration page. On the left, there's a sidebar with 'Defaults' (Project Lead: Patrick Li, Default Assignee), 'Users by role' (Roles: All, Search by name or email), and a table for 'ADMINISTRATORS' (Showing 1 of 1) with a single row for 'jira-administrators'. A modal dialog box is open over the page, titled 'Add users to a role'. It has a search field containing 'patrick', a results list showing 'Showing 1 of 1 matching users' with an item for 'Patrick Li - patrick@appfusio...', and a blue 'Add' button at the bottom. The background page is mostly white with some light gray shadows.

The users and groups assigned to the project role will be for the current project only. Each project administrator can configure this for their own projects. In this way, you can maintain project role memberships separately for each project.

JIRA permissions hierarchy

JIRA manages its permissions in a hierarchical manner. Each level is more fine-grained than the one above it. For a user to gain access to a resource, for example, to view an issue, they need to satisfy all four levels of permission (if they are all set on the issue in question):

- **Application access:** This defines the groups that will have access to the various applications in JIRA, for example, JIRA Software
- **JIRA global permission:** This permission controls the access rights functions such as overall administration
- **Project-level permission:** This permission controls the project-level permissions
- **Issue-level security:** This permission controls the view access on a per-issue level

We will now look at each of the permission levels and how you can configure them to suit your requirements, starting from the most coarse-grained permission level—global permissions.

Application access

Application access is a new concept introduced in JIRA 7. Since you now can have multiple applications in JIRA, for example, JIRA Software and JIRA Service Desk, and each application can have its own license, you as the administrator need to have a way to specify the users who will have access to each application. Prior to JIRA 7, this was controlled via the global permission JIRA Users, which is not removed. To manage application access:

1. Browse to the JIRA administration console.
2. Select the **Applications** tab and then the **Application access** option.
3. Select the group to grant access to the application. If you check the **Default** option of the group, new users will be added to the group when created:

Application access

A user must belong to a group assigned to an application to be able to log in and access that application. When you create a user for a JIRA application, that user is automatically added to the application's default group. Additional permissions can be assigned to a group via [global permissions](#).

Name	Default
jira-administrators (1 user)	<input type="checkbox"/> Remove
jira-software-users (4 users)	<input checked="" type="checkbox"/> Remove
Select group...	

Select group to add it to the application

Global permissions

Global permissions, as the name suggests, is the highest permission level in JIRA. These are coarse-grained permissions applied globally across JIRA, controlling broad security levels such as the ability to access JIRA and administer configurations.

Since they are not fine-grained security, global permissions are applied to groups rather than users. The following table lists all the permissions and what they control in JIRA:

Global permission level	Description
JIRA System Administrators	This gives the permission to perform all JIRA administration functions. This is akin to the root mode in other systems.
JIRA Administrators	This gives the permission to perform most JIRA administration functions that are not related to system-wide changes. (For example, to configure the SMTP server and to export/restore JIRA data.)
Browse Users	This gives the permission to view the list of JIRA users and groups. This permission is required if the user needs to use the User Picker/Group Picker function.
Create Shared Object	This gives the permission to share filters and dashboards with other users.
Manage Group Filter Subscriptions	This gives the permission to manage group filter subscriptions. Filters will be discussed in Chapter 10, Searching, Reporting, and Analysis .
Bulk Change	This gives the permission to perform bulk operations including the following: <ul style="list-style-type: none">• Bulk edit• Bulk move• Bulk delete• Bulk workflow transition

JIRA System Administrator versus JIRA Administrator

For people who are new to JIRA, it is often confusing when it comes to distinguishing between the JIRA System Administrator and the JIRA Administrator. For the most part, both are identical, and they can carry out most of the administrative functions in JIRA.

The difference is that JIRA administrators cannot access functions that can affect the application environment or network, while the JIRA System Administrator has access to everything.

While it can be useful to separate these two, in most cases, it is not necessary. By default, the `jira-administrators` group has both the JIRA System Administrators' and JIRA Administrators' permissions.

The following list shows examples of system operations that are only available to people with JIRA System Administrators' permission:

- Configuring SMTP server details
- Configuring CVS source code repository
- Configuring listeners
- Configuring services
- Configuring where JIRA stores index files
- Importing data into JIRA from an XML backup
- Exporting data from JIRA to an XML backup
- Configuring attachment settings
- Accessing JIRA license details
- Granting/revoking JIRA System Administrators' global permission
- Deleting users with JIRA System Administrators' global permission

Configuring global permissions

Global permissions are configured and maintained by JIRA administrators and JIRA System Administrators as follows:

1. Browse to the JIRA administration console.
2. Select the **System** tab and then the **Global permissions** option to bring up the **Global Permissions** page, shown as follows:

The screenshot shows the 'Global Permissions' page. At the top, a note states: 'These permissions apply to all projects. They are independent of project specific permissions. If you wish to set permissions on a project-by-project basis you can set them up in the [Permission Schemes](#). To allow users to log in, they must have [application access](#)'. Below this, the 'JIRA Permissions' section is displayed in a table format. The columns are 'Permissions' and 'Users / Groups'. The 'Permissions' column lists three categories: 'JIRA System Administrators', 'JIRA Administrators', and 'Browse Users'. The 'Users / Groups' column lists the groups assigned to each permission level, each with a 'View Users' and 'Delete' link.

Permissions	Users / Groups
JIRA System Administrators Ability to perform all administration functions. There must be at least one group with this permission.	• jira-administrators View Users · Delete
JIRA Administrators Ability to perform most administration functions (excluding Import & Export, SMTP Configuration, etc.).	• jira-administrators View Users · Delete
Browse Users Ability to select a user or group from a popup window as well as the ability to use the 'share' issues feature. Users with this permission will also be able to see names of all users and groups in the system.	• jira-administrators View Users · Delete • jira-servicedesk-users View Users · Delete • jira-software-users View Users · Delete

Note

Users with JIRA Administrators' global permission cannot grant themselves JIRA System Administrators' global permission.

Granting global permissions

Global permissions can only be granted to groups. For this reason, you will need to organize your users into logical groups for global permissions to take effect. For example, you will want to have all your administrators belong to a single group, such as the **jira-administrators** group, so you can grant them administration permission:

1. Browse to the **Global Permissions** page.
2. Select the permission you wish to assign from the **Add Permission** section.
3. Choose the group to be given the permission.
4. Click on the **Add** button to add the assignment.

The **Group** drop-down list will list all the groups in JIRA. It will also have an extra option called **Anyone**. This option refers to all users, including those that do not need to log in to access JIRA. You cannot select this option when granting the **JIRA Users** permission as they are required to log in, and **Anyone** refers to a non-logged in user. For a production system, it is recommended to take care when granting any global permission to **Anyone** (non-logged in users) as this can lead to security and privacy concerns. For example, by granting **Anyone** as the global permission for **Browse Users**, anyone with access to your JIRA instance will be able to get your registered users' information.

Revoking global permissions

Global permissions can also be revoked. Both the JIRA System Administrators and JIRA administrators can revoke global permissions, but JIRA administrators cannot revoke the JIRA System Administrators' global permission.

Perform the following steps to delete a global permission from a group:

1. Browse to the **Global Permissions** page.
2. Click on the **Delete** link for the group you wish to remove from the global permission.
3. Click on the **Delete** button to revoke the global permission for the group.

JIRA has built-in validation rules to prevent you from accidentally locking yourself out by mistakenly removing the wrong permissions. For example, JIRA will not let you delete the last group from JIRA System Administrators' global permissions as doing so will effectively prevent you from adding yourself back (since only JIRA System Administrators can assign/revoke global permissions).

Project permissions

As you have seen, global permissions are rather coarse in what they control and are applied globally. Since they can only be applied to groups, they are rather inflexible when it comes to deciding whom to grant the permissions to.

To provide a more flexible way of managing and designing permissions, JIRA allows you to manage permissions at the project level, which allows each project to have its own distinctive permission settings. Furthermore, permissions can be assigned to one of the following:

- **Reporter:** This is the user who submitted the issue
- **Group:** These are all users that belong to the specified group
- **Single user:** This is any user in JIRA
- **Project lead:** This is the lead of the project
- **Current assignee:** This is the user currently assigned to the issue
- **User custom field value:** This user is specified in a custom field of the type **User Custom Field**
- **Project role:** These are all users that belong to the specified role
- **Group custom field value:** These are users within the specified group in a **Group Custom Field**

The list of permissions is also more fine-grained and designed more around controlling permissions on a project level. The only catch to this is that the list is final, and you cannot add new permission types:

Project permissions	Description
Administer Project	This is the permission to administer a project. Users with this permission are referred to as project administrators. Users with this permission are able to edit the project role membership, components, versions, and general project details such as name and description.
Browse Project	This is the permission for users to browse and view the project and its issues. If a user does not have the browse project permission for a given project, the project will be hidden from them, and notifications will not be sent.
Manage Sprints	This is the permission to control who can perform sprint-related operations, such as creating and starting a sprint, on an agile board. This is only applicable to JIRA Software.

View Development Tools	This is the permission for users to have access to information from JIRA's development tools integration, such as code commits and build results.
View Read-Only Workflow	This is the permission for users to view a read-only diagram of the workflow. When the user has this permission, there will be a View Workflow link next to the issue's status.

Issue permissions	Description
Assignable User	This is the user that can be assigned to issues.
Assign Issues	This is the permission for users to assign issues to different users.
Close Issues	This is the permission for users to close issues.
Create Issues	This is the permission for users to create issues.
Delete Issues	This is the permission for users to delete issues.
Edit Issues	This is the permission for users to edit issues.
Link Issues	This is the permission for users to link issues together (if issue linking is enabled).
Modify Reporter	This is the permission for users to change the value of the Reporter field.
Move Issues	This is the permission for users to move issues.

Resolve Issues	This is the permission for users to resolve issues and set values for the Fix For Version field.
Schedule Issues	This is the permission for users to set and update due dates for issues.
Set Issue Security	This is the permission for users to set issue security levels to enable issue-level security. Refer to the following sections to learn more about issue security.
Transition Issues	This is the permission to transition issues through the workflow.

Voters and Watchers permissions	Description
Manage Watchers	This is the permission to manage the watchers' list of issues (add/remove watchers).
View Voters and Watchers	This is the permission to view the voters and watchers' list of issues.

Comments permissions	Description
Add Comments	This is the permission for users to add comments to issues.
Delete All Comments	This is the permission to delete all comments.
Delete Own Comments	This is the permission to delete your own comments.
Edit All Comments	This is the permission for users to edit comments made by all users.
Edit Own Comments	This is the permission to edit your own comments.

Attachments permissions	Description
--------------------------------	--------------------

Create Attachments	This is the permission to add attachments to issues (if an attachment is enabled).
Delete All Attachments	This is the permission to delete all attachments to issues.
Delete Own Attachments	This is the permission to delete attachments to issues added by you.

Time tracking permissions	Description
Delete Own Worklogs	This is the permission to delete worklogs made by you.
Delete All Worklogs	This is the permission to delete all worklogs.
Edit Own Worklogs	This is the permission to edit worklogs made by you.
Edit All Worklogs	This is the permission to edit all worklogs.
Work On Issues	This is the permission to log work done on issues (if time tracking is enabled).

As you can see, even though the list cannot be modified, JIRA provides you with a very comprehensive list of permissions that will cover almost all your permission needs.

With this many permissions, it will be highly inefficient if you have to create them individually for each project you have. With permission schemes, JIRA lets you define your permissions once and apply them to multiple projects.

Permission schemes

Permission schemes, like other schemes such as notification schemes, are collections of associations between permissions and users or a collection of users. Each permission scheme is a reusable, self-contained entity that can be applied to one or more projects.

Like most schemes, permission schemes are applied at the project level. This allows you to apply fine-grained permissions for each project. Just like project roles, JIRA administrators oversee the creation and configuration of permission schemes, and it is up to each project's administrator to choose and decide which permission scheme to use. This way, administrators are encouraged to design their permissions that can be reused based on the common needs of an organization. With meaningful scheme names and descriptions, project administrators will be able to choose the scheme that will fit their needs the best instead of requesting a new set of permissions to be set up for each project.

We will first look at how JIRA administrators manage and configure permission schemes and then how project administrators can apply them in their projects.

Perform the following steps to start managing permission schemes:

1. Browse to the JIRA administration console.
2. Select the **Issues** tab and then the **Permission schemes** option to bring up the **Permission Schemes** page.

 **Permission schemes** + Add permission scheme

Permission Schemes allow you to create a set of permissions and apply this set of permissions to any project. All permissions within a scheme will apply to all projects that are associated with that scheme. The table below shows the permission schemes currently configured for this server. For permissions that apply to all projects see Global Permissions.

[Learn more about project permission schemes](#)

Name	Projects	Operations
Default Permission Scheme This is the default Permission Scheme. Any new projects that are created will be assigned this scheme.	<ul style="list-style-type: none">Help DeskHuman Resource	Permissions · Copy · Edit
Default software scheme Default scheme for Software projects.	<ul style="list-style-type: none">Demonstration Project	Permissions · Copy · Edit · Delete

On the **Permission Schemes** page, you will see a list of all the permission schemes. From here, you will be able to create new schemes, edit and delete existing schemes, as well as

configure each scheme's permission settings.

Adding a permission scheme

Unlike other schemes, such as workflow schemes, JIRA does not create a project-specific permission scheme when you create a new project, but rather, it uses a preconfigured scheme called **Default Permission Scheme**. This scheme is suitable for most simple software development projects. However, it is often not enough, and it is usually a good practice to not modify the **Default Permission Scheme** directly so that you can create your own permission schemes:

1. Browse to the **Permission Schemes** pages.
2. Click on the **Add permission scheme** button.
3. Enter a name and description for the new permission scheme.
4. Click on the **Add** button to create the permission scheme.

For new permission schemes, all of the permissions will have no permission configured. This means that if you start using your new scheme straight away, you will end up with a project that nobody can access. We will look at how to configure permissions in later sections of this chapter.

Tip

It is often quicker to clone from an existing permission scheme than to start from scratch.

Configuring a permission scheme

Just like most other schemes in JIRA, you need to further fine-tune your permission scheme to make it useful:

1. Browse to the **Permission Schemes** pages.
2. Click on the **Permissions** link for the permissions scheme you wish to configure. This will take you to the **Edit Permissions** page.

On this page, you will be presented with a list of project-level permissions, along with short descriptions for each, and the users, groups, and roles that are linked to each of the permissions. You will notice that for the **Default Permission Scheme**, most of the permission options have default users linked to them through project roles. If you are looking at a new permission scheme, there will be no users linked to any of the permissions. This is your one-page view of permission settings for projects, and you will also be able to add and delete users:

The screenshot shows the 'Default Permission Scheme' configuration page. At the top, there's a lock icon, the title 'Permission schemes', and the specific title 'Default Permission Scheme'. Below that, a green button says 'SHARED BY 2 PROJECTS'. To the right are two buttons: 'Permission helper' and '+ Grant permission'. The main content area is divided into sections: 'Project permissions' and 'Issue permissions'. Each section lists a permission, its description, the users or groups it's granted to, and edit/remove buttons.

Permission	Granted to	Edit	Remove
Administer Projects Ability to administer a project in JIRA.	Project role <ul style="list-style-type: none">Administrators	Edit	Remove
Browse Projects Ability to browse projects and the issues within them.	Application role <ul style="list-style-type: none">Any logged in user	Edit	Remove
Manage Sprints Ability to manage sprints.	Project role <ul style="list-style-type: none">Administrators	Edit	Remove
View Development Tools Allows users in a software project to view development-related information on the issue, such as commits, reviews and build information.	Application role <ul style="list-style-type: none">Any logged in user	Edit	Remove
View Read-Only Workflow Users with this permission may view a read-only version of a workflow.	Application role <ul style="list-style-type: none">Any logged in user	Edit	Remove
Issue permissions			
Permission	Granted to		
Assignable User Users with this permission may be assigned to issues.	Application role <ul style="list-style-type: none">Any logged in user	Edit	Remove

Granting a permission

Like the notification schemes, JIRA offers you a range of options to specify which users should have certain permissions. You can specify users through some of the most common options such as groups, but you also have some advanced options, such as using users specified in a custom field.

Again, you have two options to grant permissions to a user. You can add them to specific permissions or multiple permissions at once. Both options will present you with the same interface and there is no difference between the two:

1. Browse to the **Edit Permissions** page for the permission scheme you wish to configure.
2. Click on the **Grant permission** button or the **Edit** link for a specific permission.
3. Select the permissions you wish to grant the user.
4. Select the user option to specify whom to grant the permission to. Click on the **Show more** link to see more options.
5. Click on the **Grant** button to grant the selected permission.

Permission options, such as **User Custom Field Value**, are a very flexible way to allow end users to control access. For example, you can have a custom field called **Editors**, and set up your **Edit Issues** permission to allow only users specified in the custom field to be able to edit issues.

The custom field does not have to be placed on the usual view/edit screens for the permission to be applied. For example, you can have the custom field appear on a workflow transition called **Submit to Manager**; once the user has selected the manager, only the manager will have permission to edit the issue.

Revoking a permission

You can easily revoke a permission given to a user, as follows:

1. Browse to the **Edit Permissions** page for the permission scheme you wish to configure.
2. Click on the **Remove** link for the permission you wish to revoke, and click on **Remove** again.

When you are trying to revoke permissions to prevent users from gaining certain access, you need to make sure no other user options are granted the same permission that might be applied to the same user. For example, if you have both the **Single User** and **Group** options set for the **Browse Projects** permission, then you will need to make sure that you revoke the **Single User** option and also make sure that the user does not belong to the **Group** option selected, so you do not have a loophole in your security settings.

Applying a permission scheme

All this time, we have been saying how permission schemes can be selected by project managers to set permissions for their projects; now, we will look at how to apply the scheme to your projects. There really is nothing special, permission schemes are applied to projects in the same way as notification and workflow schemes:

1. Browse to the project administration page you want to apply the workflow scheme to.
2. Select the **Permissions** option from the left panel.
3. Select the **Use a different scheme** option in the **Actions** menu.
4. Select the permission scheme you want to use.
5. Click on the **Associate** button.

Permission schemes are applied immediately, and you will be able to see the permissions take effect.

Issue security

We have seen how JIRA administrators can restrict general access to JIRA with global permissions, and what project administrators can do to place fine-grained permissions on individual projects through permission schemes. JIRA allows you to take things to yet another level to allow ordinary users to set the security level on the issues they are working with, with issue security.

Issue security allows users to set view permissions (not edit) on issues by selecting one of the preconfigured issue security levels. This is a very powerful feature as it allows the delegation of security control to the end users and empowers them (to a limited degree) to decide who can view their issues.

On a high level, issue security works in a similar way to permission schemes. The JIRA administrator will start by creating and configuring a set of issue security schemes with security levels set. Project administrators can then apply one of these schemes to their projects, which allow the users (with the **Set Issue Security** project permission) to select the security levels within the scheme and apply them to individual issues.

Issue security scheme

As explained earlier, the starting point of using issue security is the issue security scheme. It is the responsibility of the JIRA administrator to create and design the security levels so they can be reused as much as possible:

1. Browse to the JIRA administration console.
2. Select the **Issues** tab and then the **Issue security schemes** option to bring up the **Issue Security Schemes** page:

Issue Security Schemes

Issue Security Schemes allow you to control who can and cannot view issues. They consist of a number of security levels which can have users/groups assigned to them.

When creating/editing an issue you can specify a level of security for the issue. This ensures only users who are assigned to this security level may view the issue.

The table below shows the issue security schemes currently configured for this server. Please note that you cannot delete issue security schemes which have associated projects.

Name	Projects	Operations
DEMO: Bug Issue Security Scheme Issue security scheme for bug issues in DEMO project.	• Demonstration Project	Security Levels · Copy · Edit

Add Issue Security Scheme

Adding an issue security scheme

JIRA does not come with any predefined issue security schemes, so you will have to create your own from scratch. Perform the following steps to create a new issue security scheme:

1. Browse to the **Issue Security Schemes** page.
2. Click on the **Add Issue Security Scheme** button.
3. Enter a name and description for the new scheme.
4. Click on the **Add** button to create the new issue security scheme.

Since the issue security scheme does not define a set of security levels like the permission scheme, you will need to create your own set of security levels right after you create your scheme.

Configuring an issue security scheme

Unlike permission schemes that have a list of predefined permissions, with issue security schemes, you are in full control over how many options you want to add to the schemes.

The options within an issue security scheme are known as **security levels**. These represent the levels of security that users need to meet before JIRA will allow them access to the requested issue. Note that even though they are called security levels, it does not mean that there are any forms of hierarchy amongst the set of levels you create.

Perform the following steps to configure an issue security scheme:

1. Browse to the **Issue Security Schemes** page.
2. Click on the **Security Levels** link for the issue security scheme you wish to configure.
This will bring up the **Edit Issue Security Levels** page:

The screenshot shows the 'Edit Issue Security Levels' page. At the top, it says 'Edit Issue Security Levels' and 'SHARED BY 1 PROJECT'. Below that is a note: 'On this page you can create and delete the issue security levels for the "DEMO: Bug Issue Security Scheme" issue security scheme. Each security level can have users/groups assigned to them.' It also notes that 'An issue can then be assigned a Security Level. This ensures only users who are assigned to this security level may view the issue.' A note says 'Once you have set up some Security Levels, be sure to grant the "Set Issue Security" permission to relevant users.' There are two listed security levels: 'Internal Only (Default)' and 'Public'. Both levels have associated users/groups and operations (Add, Edit, Delete). Below this is an 'Add Security Level' section with fields for Name and Description, and a 'Add Security Level' button.

Security Level	Users / Groups / Project Roles	Operations
Internal Only (Default) Issues only visible to members of the DEMO project.	• Group (demo-project-members) (Delete)	Add · Edit · Delete
Public Issue visible to all users with access to JIRA.	• Application Role (JIRA Software) (Delete)	Add · Default · Edit · Delete

Add Security Level

Add a new security level by entering a name and description below.

Name

Description

Add Security Level

From here, you can create new security levels and assign users to existing security levels.

Adding a security level

Since issue security schemes do not define any security levels, the first step to configure your scheme would be to create a set of new security levels:

1. Browse to the **Edit Issue Security Levels** page for the issue security scheme you wish to configure.
2. Enter a name and description for the new security level in the **Add Security Level** section.
3. Click on the **Add Security Level** button.

You can add as many security levels as you like in a scheme. One good practice is to design and name your security levels based on your team or project roles, for example, developers only.

Assigning users to a security level

Similar to permission schemes, once you have your security levels in place, you will need to assign users to each of the levels. Users assigned to the security level will have permissions to view issues with the specified security level:

1. Browse to the **Edit Issue Security Levels** page.
2. Click on the **Add** link for the security level you wish to assign users to.
3. Select the option you wish to assign to the security level.
4. Click on the **Add** button to assign the users.

While it may be tempting to use the **Single User** option to add individual users, it is a better practice to use other options such as **Project Role and Group** as it is more flexible by not tying the permission to individual users and allows you to control permission with options such as group association.

Setting a default security level

You can set a security level to be the default option for issues if none are selected. This can be a useful feature for projects with a high-security requirement to prevent users (with **Set Issue Security** permission) from forgetting to assign a security level for their issues:

1. Browse to the **Edit Issue Security Levels** page.
2. Click on the **Default** link for the security level you wish to set as default.

Once set as default, the security level will have **Default** next to its name. Now, when the user creates an issue and does not assign a security level, the default security level will be applied.

Applying an issue security scheme

Just like permission schemes, the project administrators apply issue security schemes to projects. Applying the issue security scheme is similar to applying the workflow scheme, where there is an intermediate migration step involved. This is to ensure that existing issues with set issue security levels can be successfully migrated over to the new security levels in the scheme:

1. Browse to the project administration page you want to apply the workflow scheme to.
2. Select the **Issue Security** option from the left panel.
3. Select the **Use a different scheme** option in the **Actions** menu.
4. Select the permission scheme to use.
5. Click on the **Next** button to move to step 2 of the process.
6. Select the new security level to apply to the existing issue that may be affected by this change.
7. Click on the **Associate** button to apply the new issue security scheme.

Troubleshooting permissions

Just like notifications, it can be very frustrating to troubleshoot permission settings. To help with this, JIRA also provides a **Permission Helper** to assist administrators with pinpointing settings that prevent users from accessing certain features.

The **Permission Helper** works similarly to the **Notification Helper**:

1. Browse to the JIRA administration console.
2. Select the **System** tab and then the **Permission helper** option at the bottom.
3. Specify the user that is having access problems in the **User** field.
4. Specify the issue to test with.
5. Select the permission the user does not have (for example, **Edit issue**).
6. Click on **Submit**.

Permission helper

Issue Security

Patrick Li is not in security level Internal Only

Application Access

Any logged in user has this permission

Submit

As shown in the preceding screenshot, the user, **Patrick Li**, cannot edit issue **DEMO-3** because he is not in the **Internal Only** issue security level, which is required as per the **Default Permission Scheme** used.

Workflow security

The security features we have looked at thus far are not applied to workflows. When securing your JIRA, you will also need to consider who will be allowed to perform certain workflow transitions. For example, only users in the managers' group will be able to execute the **Authorize** transition on issues. For you to enforce security on workflows, you will have to set it on each transition you have by adding workflow conditions. Refer to [Chapter 7, Workflow and Business Process](#), which discusses workflows and conditions in more detail.

The HR project

In the previous chapters, you configured your JIRA to capture data with customized screens and fields, and processed the captured data through workflows. What you need to do now is secure the data you have gathered to make sure that only the authorized users can access and manipulate issues.

Since your HR project is used by the internal team, what you really need to do is put enough permission around your issues to ensure that the data they hold does not get modified by other users, by mistake. This allows us to mitigate human errors by handling access accordingly.

To achieve this, you need to have the following requirements:

- You should be able to tell who belongs to the HR team
- Restrict issue assign operations to only the user that has submitted the ticket and members of the HR team
- Do not allow issues to be moved to other projects
- Limit the assignee of tickets to the reporter and members of the HR team

Of course, there are a lot of other permissions we can apply here; the preceding four requirements will be a good starting point for us to build on further.

Setting up groups

The first thing you need to do is to set up a new group for your help desk team members. This will help you distinguish normal JIRA users from your help desk staff:

1. Browse to the **Group Browser** page.
2. Name the new group `hr - team` in the **Add Group** section.
3. Click on the **Add group** button.

You can create more groups for other teams and departments for your scenario here. Since anyone can log a ticket in your project, there is no need to make that distinction.

Setting up user group association

With your group set up, you can start assigning members of your team to the new group:

1. Browse to the **Group Browser** page.
2. Click on the **Edit members** link for the hr - team group.
3. Select users with the user picker or simply type in the usernames separated with a comma. This time, let's add our admin user to the group.
4. Click on the **Add selected users** button.

Setting up permission schemes

The next step is to set up permissions for our HR project, so you need to have your own permission scheme. As always, it is more efficient to copy the **Default Permission Scheme** as a baseline and make your modifications on top, since we are only making a few changes here:

1. Browse to the **Permission Schemes** pages.
2. Click on the **Copy** link for **Default Permission Scheme**.
3. Rename the new permission scheme **HR Permission Scheme**.
4. Change the description to **Permission scheme designed for HR team projects**.

Now that we have our base permission scheme set up, we can start on the fun part, interpreting requirements and implementing them in JIRA.

Setting up permissions

The first thing you need to do when you start setting up permissions is to try and match up with the existing JIRA permissions to your requirements. In our case, we want to restrict the following:

- Who can assign issues
- Who can be assigned to an issue
- Disable issues from being moved

Looking at the existing list of JIRA permissions, you can see that we can match up the requirements with the **Assign Issues**, **Assignable Users**, and **Move Issues** permissions, respectively.

Once you work out what permissions you need to modify, the next step is to work out a strategy to specify the users that should be given the permissions. Restricting the move issue options is simple. All you have to do is remove the permission for everyone, thus effectively preventing anyone from moving issues in your project.

The next two requirements are similar, as they are both granted to the reporter (the user that submitted the ticket) and our new **help-desk-team** group:

1. Browse to the **Permission Schemes** pages.
2. Click on the **Permissions** link for **HR Permission Scheme**.
3. Click on the **Grant permission** button.
4. Select both **Assign Issues** and **Assignable Users** permissions.
5. Select the **Reporter** option.
6. Click on the **Add** button.
7. Repeat the steps and grant the **hr-team** group both permissions.

By selecting both the permissions in one go, you have quickly granted multiple permissions to users. Now, you need to remove all the users granted with the **Move Issues** permission. There should be only one granted at the moment, **Any logged in user**, but if you have more than one, you will need to remove all of them:

1. Browse to the **Permission Schemes** page.
2. Click on the **Permissions** link for **HR Permission Scheme**.
3. Click on the **Remove** link for all the users that have been granted **Move Issues** permission.

That's it! You've addressed all our permission requirements with just a few clicks.

Putting it together

Last but not least, you can now put on your project administrator's hat and apply your new permission scheme to your **Help Desk** project:

1. Browse to the **Project Administration** page for your HR project.
2. Click on the **Permissions** option and select our new **HR Permission Scheme**.
3. Click on the **Associate** button.

By associating the permission scheme with our project, you have applied all your permission changes. Now, if you create a new issue or edit an existing issue, you will notice that the list of assignees will no longer include all the users in JIRA.

Summary

In this chapter, we first looked at how we can integrate JIRA with user repositories such as LDAP through user directories. We then looked at JIRA's user management options with groups and project roles. Though both are very similar, groups are global, while project roles are specific to each project. We also covered how JIRA hierarchically manages permissions. We discussed each permission level in detail and how to manage them.

In the next chapter, we will take a different approach and start looking at another powerful use of JIRA—getting your data out through reporting.

Chapter 10. Searching, Reporting, and Analysis

From [Chapter 2, Using JIRA for Business Projects](#), to [Chapter 6, Screen Management](#), we looked at how JIRA can be used as an information system to gather data from users.

In [Chapter 7, Workflow and Business Process](#), and [Chapter 8, E-mails and Notifications](#), we discussed some of the features that JIRA provides to add value to the gathered data through workflows and notifications. In this chapter, we will look at the other half of the equation: getting the data out and presenting it as useful information to the users.

By the end of this chapter, you will have learned the following:

- Utilizing the search interface in JIRA
- Learning the different search options available in JIRA
- Getting to know about filters and how you can share search results with other users
- Generating reports in JIRA
- Sharing information with dashboards and gadgets

Search interface and options in JIRA

As an information system, JIRA comes fully loaded with features and options to search for data. JIRA comes with three search options:

- **Quick/text search:** This allows you to search for issues quickly through simple text-based search queries
- **Basic/simple search:** This lets you specify issue field criteria via intuitive UI controls
- **Advanced search:** This lets you construct powerful search queries with JIRA's own search language, JIRA Query Language (JQL)

However, before we start looking into the in-depth details of all the search options JIRA provides, let's first take a look at the main search interface that you will be using in JIRA while performing your searches.

Issue navigator

The issue navigator is the primary interface where you will be performing all of your searches in JIRA. You can access the issue navigator by clicking on the **Issues** menu in the top menu bar and then selecting **Search for issues**.

The issue navigator is divided into several sections. The first section is where you will specify all of your search criteria, such as the project you want to search in and the issue type you are interested in. The second section shows the search results brought back. The third section includes the operations that you can perform on the search results, such as exporting them in a different format. The fourth and last section lists a number of useful, pre-configured, and user-created filters.

When you access the issue navigator for the first time, you will be in the basic search (we will discuss the different search options in more detail later in this chapter). If you previously visited the issue navigator and chose to use a different search option, such as advanced search, then JIRA will remember this and open up advanced search instead.

The following screenshot shows the issue navigator in the basic search mode. In basic search, you specify your search criteria with UI controls, selecting the values for each field:

The screenshot illustrates the JIRA Issue Navigator interface in basic search mode. It is divided into four main sections:

- 1. basic search controls:** Located at the top left, this section contains search filters for "Demonstration ...", "Type: All", "Status: All", "Assignee: All", a "Contains text" input field, and a "More" dropdown. There is also an "Advanced" button and a "toggle basic/advanced search" link.
- 2. search results:** This section displays a list of search results. The first result is titled "What is an issue?" and is associated with the "DEMO-7" issue in the "Demonstration Project / DEMO-7" project. The result includes a summary, edit, comment, assign, and more buttons, and a "Details" panel.
- 3. search result operations:** Located at the top right, this section includes "Share", "Export", and "Tools" dropdown menus, and a "1 of 5" page indicator.
- 4. pre-configured & favorited filters:** A sidebar on the left containing a "FILTERS" header, a "New filter" button, and a list of filters: "Find filters", "My Open Issues", "Reported by Me", "Recently Viewed", "All Issues", "Open Issues", "Added recently", "Resolved recently", "Updated recently", and "FAVORITE FILTERS" (which is empty).

The "Details" panel for the "What is an issue?" result shows the following information:

Details	Description	Operations
Type:	Story	Status: OPEN
Priority:	Medium	(View Workflow)
Labels:	None	Resolution: Unresolved
Department:	Engineering	
Description		update issues from search result
Different organizations use JIRA to track different kinds of issues. Depending on how your organization is using JIRA, an issue could represent a software bug, a project task, a helpdesk ticket, a leave request form, etc.		

The "Operations" panel on the right side of the details panel includes:

- People:** Shows assignee (Kim Lee), reporter (Patrick Li), and watchers.
- Dates:** Shows created (2 minutes ago) and updated (Just now).
- Agile:** Shows Agile status.

Basic search

This is also known as simple search. Basic search allows you to construct your search criteria with a simple-to-use interface. The basic search interface lets you select the fields you want to search with, such as issue status, and specify the values for these fields. As shown in the following screenshot, we are searching for issues in the **Demonstration Project**, and with the status as **Open**.

With basic search, JIRA will prompt you for the possible search values for the selected field. This is very handy for fields such as status and select list-based custom fields, so you do not have to remember all the possible options. For example, for the status field, JIRA will list all the available statuses, as shown in the following screenshot:

The screenshot shows the JIRA basic search interface. At the top, there are filters for 'Project: Demonstration ...' and 'Type: All'. Below these are buttons for 'Open', 'Assignee: All', 'Contains text', and a 'More' button, which is highlighted with a red box. A search bar labeled 'Find Statuses...' with a magnifying glass icon is next. To the right, a list of statuses is displayed: OPEN (selected), IN PROGRESS, REOPENED, RESOLVED, and CLOSED. On the far right, there are buttons for 'Sign', 'More', 'Resolve Issue', and 'Close Issue'. Below the status list, there are sections for 'Status:' (OPEN) and 'Resolution:' (Unresolved). The left sidebar shows a list of issues: DEMO-7, DEMO-6, DEMO-5, and DEMO-2, each with a checkbox and a link to 'What is an issue?'. There are also links for 'Keyboard shortcuts' and 'Editing issues'.

While working with the basic search interface, JIRA will have the default fields of project, issue type, status, and assignee visible. You can add additional fields to the search by clicking on the **More** button and then selecting the field you want to use in the search. Perform the following steps to construct and run a basic search:

1. Browse to the **Issue Navigator** page. If you do not see the basic search interface, and the **Basic** link is showing, click on it to switch to basic search.
2. Select and fill in the fields in the basic search interface. You can click on **More** to add more fields to the search criteria.

JIRA will automatically update the search results every time you make a change to the search criteria.

Note

When working with basic search, one thing to keep in mind is that the project and issue type **context** of the custom fields are taken into consideration (please see [Chapter 5, Field Management](#), for field configuration). If a custom field is set to be applicable to only specific projects and/or issue types, you have to select the project and issue type as part of your search for the custom field to show up.

Advanced search with JQL

Basic search is useful and will fulfill most of the users' search needs. However, there are still some limitations. One such limitation is that basic search allows you to perform searches based on inclusive logic but not exclusive logic. For example, if you need to search for issues in all but one project, with basic search, you will have to select every project except for the one to be excluded, since the basic search interface does not let you specify exclusions, and this is where advanced search comes in.

With advanced search, instead of using a field selection-based interface as in basic search, you will be using what is known as the **JIRA Query Language (JQL)**. JQL is a custom query language developed by Atlassian. If you are familiar with the **Structured Query Language (SQL)**, you will notice that it has a similar syntax; however, JQL is not the same as SQL.

One of the most notable differences between JQL and SQL is that JQL does not start with a select statement. A JQL query consists of a field followed by an operator, and then by a value or a function (which will return a value). You cannot specify what fields to return from a query with JQL, which is different from SQL. You can think of a JQL query as the part that comes after the `where` keyword in a normal SQL select statement. The following table summarizes the components in JQL:

JQL component	Description
Keyword	<p>Keywords in JQL are special reserved words that do the following:</p> <ul style="list-style-type: none">• Join queries together, such as AND• Determine the logic of the query, such as NOT• Have special meaning, such as NULL• Provide specific functions, such as ORDERBY
Operator	<p>Operators are symbols or words that can be used to evaluate the value of a field on the left and the values to be checked on the right.</p> <p>Examples include the following:</p> <ul style="list-style-type: none">• Equals: =• Greater than: >• IN: When checking whether the field value is in one of the many values specified in parentheses
	Fields are JIRA system and custom fields. When used in JQL, the value of the

Field	field for issues is used to evaluate the query.
Functions	Functions in JQL perform specific calculations or logic and return the results as values that can be used for evaluation with an operator.

Each JQL query is essentially made up of one or more components. A basic JQL query consists of the following three elements:

- **Field:** This can be an issue field (for example, status) or a custom field.
- **Operator:** This defines the comparison logic (for example, = or >) that must be fulfilled for an issue to be returned in the result.
- **Value:** This is what the field will be compared to; it can be a literal value expressed as text (for example, Bug) or a function that will return a value. If the value you are searching for contains spaces, you need to put quotes around it, for example, issuetype = "New Feature".

Queries can then be linked together to form a more complex query with keywords such as logical AND or OR. For example, a basic query to get all the issues with a status of Resolved will look similar to the following:

```
status = Resolved
```

A more complex query to get all the issues with a Resolved status and a Bug issue type, which is assigned to the currently logged-in user, will look similar to the following (where currentUser() is a JQL function):

```
issuetype = Bug and status = Resolved and assignee = currentUser()
```

Discussing each and every JQL function and operator is out of the scope of the book, but you can get a full reference by clicking on the **Syntax Help** link in the advanced search interface. The full JQL syntax reference can be found at <https://confluence.atlassian.com/x/ghGyCg>.

You can access the advanced search interface from the **Issue Navigator** page, as follows:

1. Browse to the **Issue Navigator** page.
2. Click on the **Advanced** link on the right.
3. Construct your JQL query.
4. Click on the **Search** button or press the **Enter** key on your keyboard.

As JQL has a complex structure and it takes some time to get familiar with, the advanced search interface has some very useful features to help you construct your query. The interface has an **autocomplete** feature (which can be turned off from the General Configuration setting.) that can help you pick out keywords, values, and operators to use. It also validates your query in real time and informs you whether your query is valid, as shown in the

following screenshot:

The screenshot shows a JIRA search interface. The search bar at the top contains the query: "project = DEMO AND status =". The results table has columns: Assignee, Reporter, P, Status, Resolution, Created, Updated, and Due. There are four rows of results. The first row is highlighted in blue and shows: Assignee Kim Lee, Reporter Patrick Li, P OPEN, Status Unresolved, Resolution Unresolved, Created 01/Oct/16, Updated 01/Oct/16, and Due. The second row shows: Assignee Unassigned, Reporter Patrick Li, P OPEN, Status Unresolved, Resolution Unresolved, Created 01/Oct/16, Updated 01/Oct/16, and Due. The third row shows: Assignee Unassigned, Reporter Patrick Li, P OPEN, Status Unresolved, Resolution Unresolved, Created 01/Oct/16, Updated 01/Oct/16, and Due. The fourth row shows: Assignee Unassigned, Reporter Patrick Li, P OPEN, Status Unresolved, Resolution Unresolved, Created 18/Sep/16, Updated 18/Sep/16, and Due. A sidebar on the left lists filter options: Closed, Collecting Assets, Done, In Exit Review, In Progress, Open, Reopened, Resolved, To Do, and Syntax Help.

Assignee	Reporter	P	Status	Resolution	Created	Updated	Due
Kim Lee	Patrick Li	OPEN	Unresolved	01/Oct/16	01/Oct/16		...
Unassigned	Patrick Li	OPEN	Unresolved	01/Oct/16	01/Oct/16		
Unassigned	Patrick Li	OPEN	Unresolved	01/Oct/16	01/Oct/16		
ion and how does it work?	Unassigned	Patrick Li	OPEN	Unresolved	18/Sep/16	18/Sep/16	

If there are no syntax errors with your JQL query, JIRA will display the results in a table below the JQL input box.

You can switch between the basic and advanced search by clicking on the **Basic/Advanced** link while running your queries, and JIRA will automatically convert your search criteria into and from JQL. In fact, this is a rather useful feature and can help you learn the basic syntax of JQL when you are first starting up, by first constructing your search in basic and then seeing what the equivalent JQL is. You need to take note, however, that not all JQLs can be converted into basic search since you can do a lot more with JQL than with the basic search interface.

Tip

Switching between simple and advanced search can help you get familiar with the basics of JQL.

Quick search

JIRA provides a quick search functionality, which allows you to perform quick simple searches based on the text contained in the issue's summary, description, or comments. This allows you to perform quick text-based searches on all issues in JIRA.

The quick search function has several additional features to let you perform more specialized searches with minimal typing, through smart querying. JIRA has a list of built-in queries, which you can use as your quick search terms to pull up issues with a specific issue type and/or status. Some useful queries are included in the following table (you can find the full quick search reference at <https://confluence.atlassian.com/jiracoreserver072/quick-searching-829092656.html>:)

Smart query	Result
Issue key (for example, HD-12)	Takes you directly to the issue with the specified issue key.
Project key (for example, HD)	Displays all the issues in the project specified by the key in the Issue Navigator page.
my or my open bugs	Displays all the issues that are assigned to the currently logged-in user.
overdue	Displays all the issues that are due before today.
Issues with a particular status (for example, open)	Displays all issues with the specified status.
Issues with a particular resolution (for example, resolved)	Displays all issues with the specified resolution.

You can combine these queries together to create quick yet powerful searches in JIRA. For example, the following query brings back all the resolved issues in the **Help Desk** project:

HD resolved

Running a quick search is much simpler than either basic or advanced searches. All you have to do is type in either the text you want to search with or the smart query in the **Quick Search** box in the top-right corner, and click on **Enter** on your keyboard.

As you can see, the goal of quick search is to allow you to find what you are looking for in the quickest possible way. With smart query, you are able to perform more than just simple text-based searches.

Note

It is important to note that quick search is case sensitive. For example, searching with the term `My` instead of `my` will become a simple text search rather than issues that are assigned to the currently logged-in user.

Working with search results

You have seen how you can execute searches in JIRA. With the exception of using the issue key smart query, which will take you directly to the target issue, all other search results will be shown in the issue navigator.

The issue navigator is capable of more than letting you run searches and presenting you with the results; it also has other features which allow you to:

- Display search results in different view options
- Export search results into different formats
- Select the columns you want to see for the issues in the results
- Share your search results with other people
- Create and manage filters

Switching result views

The issue navigator can display your search results in two different views. The default view is **Detail View**, where issues from results are listed on the left-hand side, and the currently selected issue's details are displayed on the right. This view allows you to view the issue's contents on the same page as the search result.

The second view is **List View**, where issues are listed in a tabular format. The issue's field values are displayed as table columns. As you will see later, you can configure the table columns as well as the way they are ordered. You can switch between the two views by selecting the options from the **Views** menu next to the **Basic/Advanced** option.

Exporting search results

From the issue navigator, JIRA allows you to export your search results to a variety of formats, such as MS Word and Excel. JIRA is able to present your search results in different formats, such as XML or print-friendly pages. When you select formats such as Word or Excel, JIRA will generate the appropriate file and let you download it directly. Perform the following steps to export your results to a different format:

1. Browse to the **Issue Navigator** page.
2. Execute a search.
3. Select the **Export** drop-down menu in the top-right corner.
4. Select the format you wish to see your search results in.

Depending on the format you select, some formats will be on screen (for example, printable), while others will prompt you with a download dialog box (for example, Excel).

Customizing the column layout

If you are using the **List View** option to display your search results, you configure the field columns to be displayed. In JIRA, you can customize your issue navigator for all your personal searches and also on a per-search level with filters (see later in this chapter). If you are an administrator, you can set the column layout for other users too (which can be overwritten by each user's own column layout settings).

Perform the following steps to customize your global issue navigator's column layout:

1. Browse to the **Issue Navigator** page.
2. Change your result view to **List View**.
3. Select the **Columns** drop-down menu and a column layout option, as shown next:

The screenshot shows the JIRA Issue Navigator interface with a search filter for 'project = DEMO AND status = Open'. On the right, a 'Columns' dialog box is open, showing a list of available columns: Assignee, Created, Due Date, Issue Type, and Key. The 'Assignee' column is checked and highlighted in blue. Other columns like 'Created' and 'Due Date' are also checked. Buttons for 'Done' and 'Cancel' are at the bottom of the dialog.

The following options can be used to lay out the columns:

- **My Defaults:** This column layout will be applied to all your searches
- **Filter:** This column layout will be applied only to the current filter
- **System:** This column layout will be applied to all searches

To add or remove a field column, simply check or uncheck the field from the list. To reorder the column layout, you can drag the columns left or right to their appropriate locations.

Sharing search results

After completing a search, you may want to share the results with your colleagues. Now you can tell your colleagues to run the same search or, as we will see later in the chapter, save your search as a filter and then share it with other people. Alternatively, a more convenient way is to use the built-in share feature, especially if this is a one-off sharing.

To share your current search results, all you have to do is click on the **Share** button in the top-right corner and type in the user's name or an e-mail address (using an e-mail address lets you share your search results with people who are not JIRA users), and you can add multiple users or e-mail addresses, so you can share this with more than one person. You can also add a quick note, letting people know why you are sharing the search results with them, and JIRA will send out e-mails to all the selected users and e-mail addresses.

Filters

After you have run a search query, sometimes it will be useful to save the query for later use. For example, you may have created a query to list all the open bugs and new features in a project that are to be completed by a certain date in several projects so you can keep an eye on their progress. Instead of recreating this search query every time you want to check up on the statuses, you can save the query as a filter, which can be reused at a later stage. You can think of filters as named search queries that can be reused.

Other than being able to quickly pull up a report without having to recreate the queries, saving search queries as filters provides you with other benefits, including the following:

- Share saved filters with other users
- Use the filters as a source of data to generate reports
- Use the filters for agile boards (see [Chapter 3, Using JIRA for Agile Projects](#))
- Display results on a dashboard as a gadget
- Subscribe to the search queries to have results e-mailed to you automatically

A few things to keep in mind when creating and using filters as the data source for gadgets and agile boards are as follows:

- When you are creating a filter for agile boards, make sure you select the relevant projects as part of your search query.
- When you are creating a filter for gadgets and agile boards, make sure you share the filter with the same group of users that has access to the gadgets and boards. Otherwise, they will not see any results.

We will explore all of the advanced operations you can perform with filters, and explain some of the new terms and concepts, such as dashboard and gadgets, in later sections. However, let's look at how we can create and manage filters first.

Creating a filter

To create a new filter, you will first have to construct and execute your search query. You can do this with any of the three available search options provided in JIRA, but please note that the search result must bring you to the **Issue Navigator** page. If you are using the quick search option and search by issue key, you will not be able to create a filter. Once you have executed your query, regardless of whether it brings back any result, you will be able to create a new filter based on the executed search:

1. Browse to the **Issue Navigator** page.
2. Construct and execute a search query in JIRA.
3. Click on the **Save as** button at the top.
4. Enter a meaningful name for the filter.
5. Click on the **Submit** button to create the filter.

Once you have created the filter, all your search parameters will be saved. In future, when you rerun the saved filter, JIRA will retrieve the updated results based on the same parameters.

Take note that you need to click on the **New filter** button to start a new search if you have created a filter. Since the issue navigator remembers your last search, if you were working with an existing filter, without starting a new search, you will in fact be modifying the current filter instead.

Tip

Always click on the **New filter** button to start a new search session to avoid accidentally modifying an existing filter.

Managing filters

As the number of created filters grows, you will need a centralized location to manage and maintain them. There are two ways to access the **Manage Filters** page. You can access the page through the issue navigator, as follows:

1. Browse to the **Issue Navigator** page.
2. Click on the **Find filters** link at the left-hand side. You can also access the **Manage Filters** page by going through the top navigator bar.
3. Bring the drop-down menu from **Issues**.
4. Click on the **Manage filters** option at the bottom of the list.

The **Manage Filters** page displays the filters that are visible to you in three main categories, as set out in the tabs to the left, along with the option to search for existing filters:

- **Favorite:** This option lists filters with a gray star next to their names. These filters will be listed in the **Issues** drop-down menu. You can mark a filter as a favorite by clicking on the star directly.
- **My:** This option lists the filters that are created by you.
- **Popular:** This option lists the top 20 filters that have the most people marking them as favorite.
- **Search:** This option searches for existing filters that are shared by other users.

As shown in the following screenshot, both the **Due this week (HD)** and **Due this week (HR)** filters are marked as favorites:

Name	Shared With	Subscriptions
★ Due this week (HD)	• Project: Help Desk	None - Subscribe
★ Due this week (HR)	• Project: Human Resource	None - Subscribe
★ Filter for DEMO board	• Project: Demonstration Project	None - Subscribe
★ Highest priority and open (HD)	• Project: Help Desk	None - Subscribe
★ Highest priority and open (HR)	• Project: Human Resource	None - Subscribe

Sharing a filter

After creating a filter, you can update its details such as name and description, sharing permission, and search parameters. By default, newly created filters are not shared, which means they are only visible to you. To share your filters with other users, perform the following steps:

1. Browse to the **Manage Filters** page.
2. Click on the **Edit** option for the filter you wish to edit.
3. Update the details of the filter.
4. Select the group/project role to share the filter with.
5. Click on the **Save** button to apply the changes.

This is shown in the following screenshot:

Edit Current Filter

Sharing with everyone will make this public and visible to users who are not logged in.

Project: Human Resource

Add Shares

Everyone

+ Add

Shared with everyone

Save

Cancel

Note

Make sure you click on the **Add** link after you have chosen a group or a project to share the filter with.

For you to be able to share a filter, you will also need to have the **Create Shared Object** global permissions (please refer to [Chapter 9, Securing JIRA](#), for more information on global permissions).

After you have shared your filter, other users will be able to search for it and subscribe to it. However, they will not be able to make changes to your filter. Only the owner of the filter is

able to make changes to its search parameters. As we will see later, JIRA administrators can also change the ownership of filters.

Subscribing to a filter

You have seen in [Chapter 8, E-mails and Notifications](#), that JIRA is able to send out e-mails when certain events occur to keep the users updated. With filters, JIRA takes this feature one step further by allowing you to subscribe to a filter.

When you subscribe to a filter, JIRA will run a search based on the filter and send you the results in an e-mail. You can specify the schedule of when and how often JIRA should perform this. For example, you can set up a subscription to have JIRA send you the results every morning before you come to work so when you open up your mail inbox, you will have a full list of issues that require your attention.

To subscribe to a filter, you will need to be able to see the filter (either created by you, or shared with you by other users):

1. Browse to the **Manage Filters** page.
2. Locate the filter you wish to subscribe to.
3. Click on the **Subscribe** link for the filter.
4. Select the recipient of the subscription. Normally, this will be you (**Personal Subscription**). You can also create subscriptions for other people by selecting a group.
5. Check the **Email this filter even if there are no issues found** option if you wish to have an e-mail sent to you if there are no results returned from the filter. This can be useful to make sure that the reason you are not getting e-mails is not due to other errors.
6. Specify the frequency and time when JIRA can send you the e-mails.

This is shown in the following screenshot:

- Click on the **Subscribe** button. This will create the subscription and take you back to the **Manage Filters** page. The **Subscribe** link will increment the number of subscriptions; for example, **1 Subscription**.
- Click on the **1 Subscription** link to verify the subscription is created correctly.
- Click on the **Run now** link to test your new subscription:

Subscriptions

Add subscription

Subscriber	Subscribed	Schedule	Last sent	Next send	Operations
Patrick Li	Patrick Li	Daily at 1:00 am	Never	05/Nov/16 1:00 AM	Edit · Delete · Run now

Deleting a filter

You can delete a filter when it is no longer needed. However, since you can share your filters out with other users and they can create subscriptions, you need to keep in mind that if you are deleting a shared filter, you may impact other users. Luckily, when you delete a filter, JIRA will inform you if other people are using the filter:

1. Browse to the **Manage Filters** page.
2. Click on the **Delete** link for the filter you wish to remove. This will bring up the **Delete Filter** confirmation dialog box.
3. Make sure that the removal of the filter will not impact other users.
4. Click on the **Delete** button to remove the filter.

JIRA will inform you if there are users subscribed to the filter. You can click through to see the list of subscribers, and then decide to either proceed with deleting the filter and letting the other users know or leave the filter in JIRA.

Changing the ownership of a filter

JIRA only allows the filter's owner to make changes, such as in the search criteria. This is usually not a problem in most cases, but when a filter is shared with other users, this can be problematic when the owner leaves the organization. Perform the following steps to change a filter's ownership:

1. Browse to the JIRA Administration console.
2. Select the **System** tab and then the **Shared filters** option.
3. Search for the filter you wish to change ownership of.
4. Click on the **Change Owner** option.
5. Search and select the user that will be the new owner.
6. Click on the **Change Owner** button.

This is shown in the following screenshot:

The screenshot shows the 'Search Shared Filters' interface. At the top, there are search fields for 'Search' and 'Owner'. Below these are buttons for 'Search' and 'Clear'. A note says 'Start typing to get a list of possible matches.' The main area displays a table of filters. The columns are 'Name', 'Owner', 'Shared With', and 'Popularity'. The first filter, 'Due this week (HD)', has its 'Owner' field set to 'Patrick Li (patrick)'. In the 'Shared With' column, there is a dropdown menu with two items: 'Project: Help Desk' and 'Project: Human Resource'. To the right of the table, there are two more columns: 'Popularity' (with values 1 and 0) and 'More Options' (with gear icons). A context menu is open over the first filter's row, showing options 'Change Owner' and 'Delete Filter'. The 'Change Owner' option is highlighted with a blue background.

Name	Owner	Shared With	Popularity
Due this week (HD)	Patrick Li (patrick)	• Project: Help Desk	1
Due this week (HR)	Patrick Li (patrick)	• Project: Human Resource	
Filter for DEMO board	Patrick Li (patrick)	• Project: Demonstration Project	0

Reports

Apart from JQL and filters, JIRA also provides specialized reports to help you get a better understanding of the statistics for your projects, issues, users, and more. Most reports in JIRA are designed to report on issues from a specific project; however, there are some reports that can be used globally across multiple projects, with filters.

Generating a report

All JIRA reports are accessed from the **Browse Project** page of a specific project, regardless of whether the report is project-specific or global. The difference between the two types of reports is that a global report will let you choose a filter as a source of data, while a project-specific report will have its source of data predetermined based on the project you are in.

When generating a report, you will often need to supply several configuration options. For example, you may have to select a filter, which will provide the data for the report, or select a field to report on. The configuration options vary from report to report, but there will always be hints and suggestions to help you work out what each option is.

Perform the following steps to create a report; you will first need to get to a project's browse page:

1. Select the project you wish to report on.
2. Click on the **Reports** option from the left panel.
3. Select the report you wish to create. The types of reports available will vary depending on the project type.
4. Specify the configuration options for the report.
5. Click on the **Next** button to create the report.

In the following example, we will create a pie chart report. We will first select the type of report to be generated by selecting it from a list of available report types that come with JIRA, as shown in the following screenshot:

The screenshot shows the 'All reports' section of the JIRA interface. It displays three report types under the 'Issue analysis' heading:

- Average Age Report**: Shows a bar chart of average issue ages.
- Created vs. Resolved Issues Report**: Shows a line chart comparing created and resolved issues over time.
- Pie Chart Report**: Shows a pie chart of issue breakdown by category.

Each report type has a brief description below it.

Report Type	Description
Average Age Report	Shows the average age of unresolved issues for a project or filter. This helps you see whether your backlog is being kept up to date.
Created vs. Resolved Issues Report	Maps created issues versus resolved issues over a period of time. This can help you understand whether your overall backlog is growing or shrinking.
Pie Chart Report	Shows a pie chart of issues for a project/filter grouped by a specified field. This helps you see the breakdown of a set of issues, at a glance.

We will then configure the necessary report parameters. In this case, you need to specify

whether you are generating a report based on a project or an existing filter; by default, the current project will be preselected. You also need to specify which issue field you will be reporting on, as you can see from the following screenshot:

Configure - Pie Chart Report

Report: Pie Chart Report

Description:
Shows a pie chart of issues for a project/filter grouped by a specified field. This helps you see the breakdown of a set of issues, at a glance.

Project or Saved Filter [Demonstration Project](#) [Change Filter or Project...](#)

Filter
Project or saved filter to use as the basis for the graph.

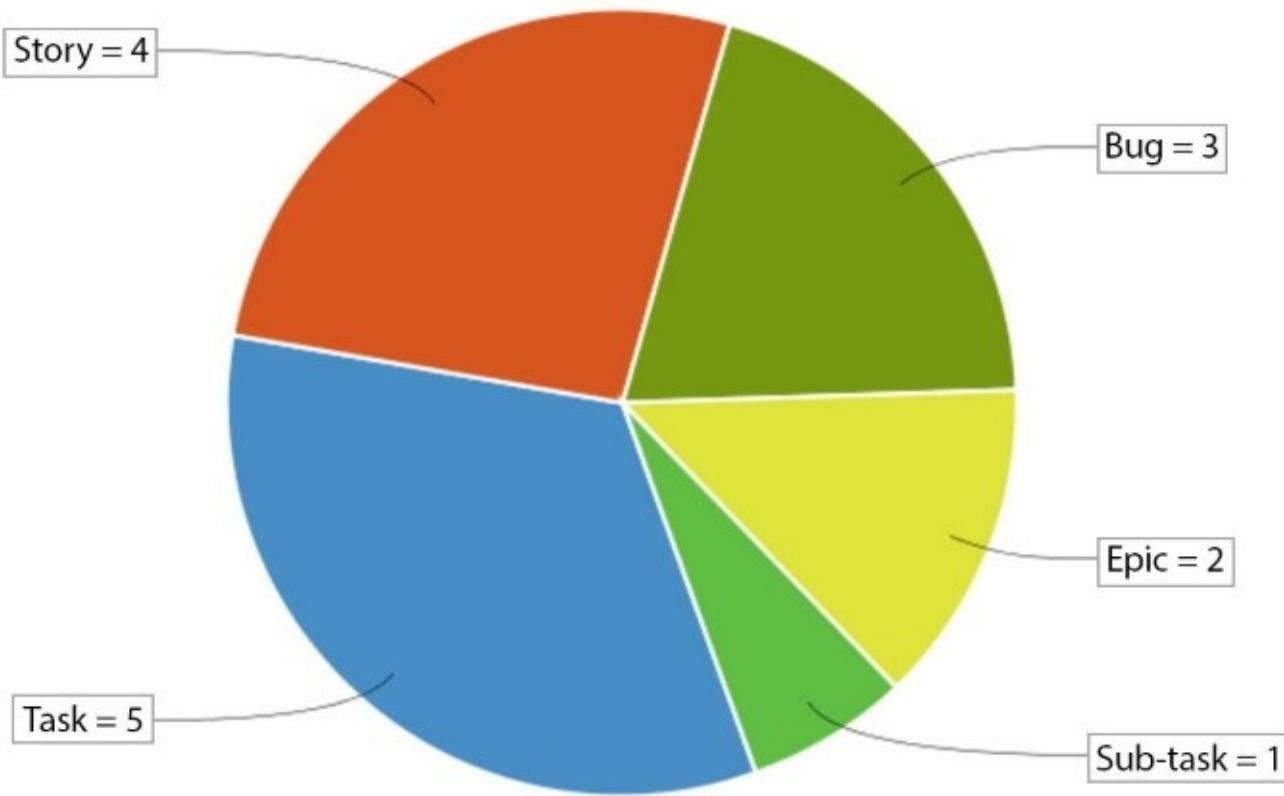

Statistic Type [Issue Type](#)
Select which type of statistic to display for this filter

[Next](#) [Cancel](#)

Once you have configured the report and clicked on the **Next** button, JIRA will generate the report and present it on the screen, as shown in the following figure:

Project: Demonstration Project (Issue Type)

Chart

Data Table

	Issues	%
Task	5	33%
Story	4	26%
Bug	3	20%
Epic	2	13%
Sub-task	1	6%

The report type determines the report's layout. Some reports have a chart associated with them (for example, **Pie Chart Report**), while other reports will have a tabular layout (for

example, **Single Level Group By Report**). Some reports will even have an option for you to export its content into formats such as Microsoft Excel (for example, **Time Tracking Report**).

Dashboards

The dashboard is the first page you see when you access JIRA. Dashboards host mini-applications known as **gadgets**, which provide various data and information from your JIRA instance. The dashboard acts as a portal, which provides users with a quick one-page view of information that is relevant or of interest to them.

Managing dashboards

When you first install JIRA, the default dashboard you see is called the **system dashboard**, and it is pre-configured to show some useful information, such as all issues that are assigned to you:

1. Since everyone shares the system dashboard, you as a normal user cannot make changes to it, but you can create your own dashboards. Each dashboard's functions are configured independently.
2. Bring down the drop-down menu from **Dashboards**.
3. Select the **Manage Dashboards** option. This will bring you to the **Manage Dashboards** page, as shown in the following screenshot:

The screenshot shows the 'Manage Dashboards' page. On the left, there is a sidebar with tabs: 'Favorites', 'My Popular Search'. The main area is titled 'My Dashboards' with a sub-instruction: 'This page allows you to manage all dashboards you own.' Below this is a table with columns 'Name' and 'Shared With'. Three dashboards are listed: 'Customer Portal' (marked with a star), 'Demo Dashboard', and 'Help Desk'. Each row has a gear icon for configuration.

Name	Shared With
★ Customer Portal	• Private Dashboard
★ Demo Dashboard	• Private Dashboard
★ Help Desk	• Private Dashboard

From this page, you can edit and maintain dashboards created by you, search dashboards created and shared by others, and mark them as favorite so that they will be listed as tabs for easy access.

When a dashboard is marked as favorite by clicking on the star icon in front of its name, the dashboard will be accessible when you click on the **Dashboards** link at the top menu bar. If you have more than one favorite dashboard, each will be listed in the tabs and you can select which one to display.

Creating a dashboard

The default **System Dashboard** cannot be changed by normal users, so if you want to have a personalized dashboard displaying information that is specific to you, you will need to create a new dashboard. Perform the following steps to create a new dashboard:

1. Browse to the **Manage Dashboards** page.
2. Click the **Create new dashboard** button.
3. Enter a meaningful name and description for the new dashboard.
4. Select whether you wish to copy from an existing dashboard or start with a blank one. This is similar to creating a new screen from scratch or copying an existing screen.
5. Select whether or not the new dashboard will be a favorite dashboard (for easy access) by clicking on the star icon.
6. Select whether you wish to share the dashboard with other users. If you share your dashboard with everyone by choosing the **Everyone** option, then users that are not logged in will also be able to see your dashboard.
7. Click on the **Add** button to create the dashboard.

The following screenshot shows how you can create a new dashboard from scratch (blank dashboard) and share it with the members of the **jira-software-users** group, which, by default, are all logged-in users for JIRA Software:

Create New Dashboard

Name *

Description

Start From Blank dashboard ▼

Choose a dashboard whose gadgets will be copied to the new dashboard.
Alternatively, choose 'Blank dashboard' to create a dashboard with no gadgets.

Favorite

Shares Group: jira-software-users Delete

Add Shares Group ▼ jira-software-users ▼ + Add

Shared with everyone in the 'jira-software-users' group

Add Cancel

For you to be able to share a dashboard, you will also need to have the **Create Shared Object** global permissions (please refer to [Chapter 9, Securing JIRA](#), for more information on global permissions).

Once you have created the new dashboard, you will be taken immediately to it. As the owner of the new dashboard, you will be able to edit its layout and add gadgets to it. We will be looking at these configuration options in the next section.

Configuring a dashboard

All custom created dashboards can be configured once they have been created. As the owner, there are two aspects of a dashboard you can configure:

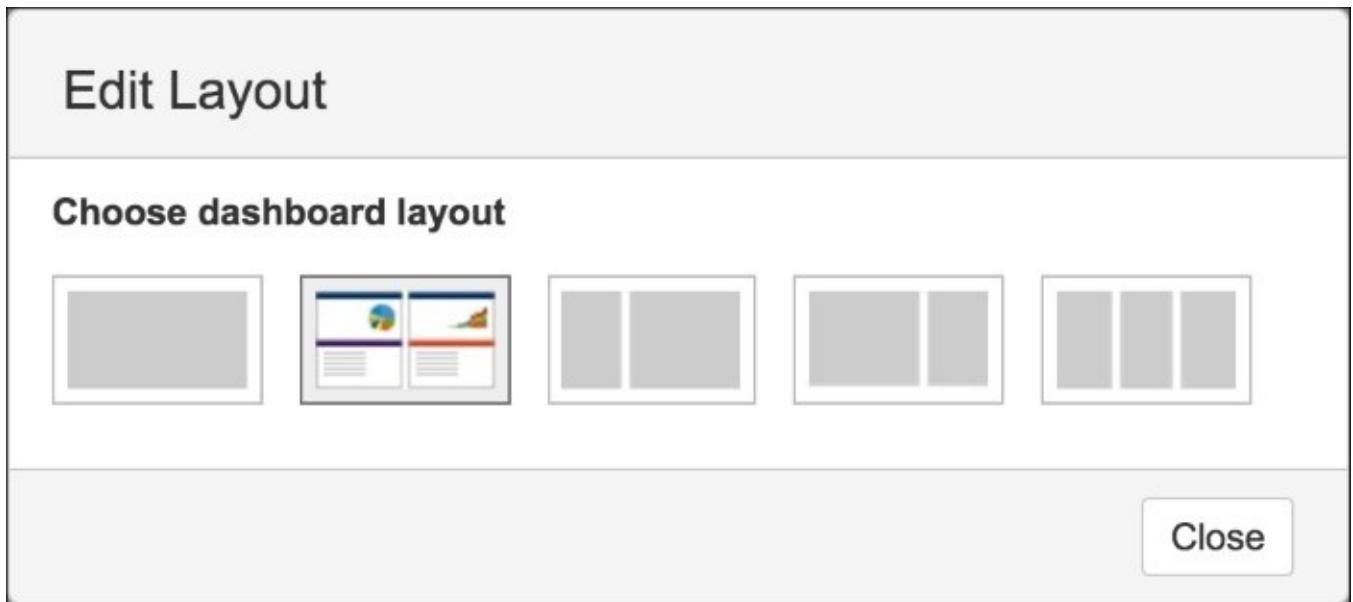

- **Layout:** This describes how the dashboard page will be divided
- **Contents:** This describes the gadgets that are to be added to the dashboard

Setting a layout for the dashboard

You have to be the owner of the dashboard (created by you) to set the layout. Setting a dashboard's layout is quite simple and straightforward. If you are the owner, you will have the **Edit Layout** option at the top-right corner while you view the dashboard.

JIRA comes with five layouts that you can choose from. These layouts differ in how the dashboard page's on-screen real estate is divided. By default, new dashboards have the second layout that divides it into two columns of equal size:

1. Bring up the drop-down menu from **Dashboards**.
2. Select the dashboard you wish to edit the layout for.
3. Click on the **Edit Layout** option at the top-right corner. This will bring up the **Edit Layout** dialog.
4. Select the layout you wish to change to:

A layout selected from the dialog box will be immediately applied to the dashboard. Any existing contents will automatically have their size and positions adjusted to fit the new layout.

After you have decided on your dashboard's layout, you can start adding contents, known as

gadgets, onto your dashboard. Before you get to that, let's first take a brief look at what gadgets are.

Changing the ownership of a dashboard

As with filters, the JIRA administrator can change the ownership of a dashboard to a different user, in case the original user has left the organization. Perform the following steps to change a dashboard's ownership:

1. Browse to the JIRA administration console.
2. Select the **System** tab and then the **Shared dashboards** option.
3. Search for the dashboard you wish to change ownership of.
4. Click on the **Change Owner** option.
5. Search and select the user that will be the new owner.
6. Click on the **Change Owner** button, as shown in the following screenshot:

The screenshot shows the 'Search Shared Dashboards' interface. At the top, there are search fields for 'Search' and 'Owner'. Below these are buttons for 'Search' and a gear icon. The main area displays a table of dashboards with columns: Name, Owner, Shared With, and Popularity. Two dashboards are listed: 'Customer Portal' (Owner: Patrick Li (patrick)) and 'Help Desk' (Owner: Patrick Li (patrick)). For the 'Help Desk' row, a context menu is open, with the 'Change Owner' option highlighted in blue. Other options in the menu include 'Delete Dashboard'.

Name	Owner	Shared With	Popularity
Customer Portal	Patrick Li (patrick)	• Shared with everyone	1

Gadgets

Gadgets are like mini-applications that live on a dashboard in JIRA. They are similar to widgets in most of the smart phones we have today or portlets in most portal applications. Each gadget has its own unique interface and behavior. For example, the **Pie Chart** gadget displays data in a pie chart, while the **Assigned to Me** gadget lists all the unresolved issues that are assigned to the current user in a table.

To discuss the in-depth details of gadgets and their underlying technology (OpenSocial) is beyond the scope of this book, but there is much information on this topic available on the Internet, if you are interested in creating your own gadgets to use with JIRA. A good place to start will be the Atlassian documentation at <https://developer.atlassian.com/x/IgA3>.

Placing a gadget on the dashboard

All gadgets are listed in the **Gadget Directory**. JIRA comes with a number of useful gadgets, such as the **Assigned to Me** gadget that you see on the **System Dashboard**. The following screenshot shows the gadget directory, listing all the bundled gadgets in JIRA.

Perform the following steps to place a gadget onto your dashboard:

1. Bring up the drop-down menu from **Dashboards**.
2. Select the dashboard you wish to add a gadget to.
3. Click on the **Add Gadget** option at the top-right corner. This will bring up the **Gadget Directory** window.
4. Click on the **Add gadget** button for the gadget you wish to add.
5. Click on the **Close** link to return to the dashboard, as shown in the following screenshot:

The screenshot shows the 'Add a gadget' page in the JIRA Gadget Directory. On the left, there is a search bar and a sidebar with categories: All (31), Charts (8), JIRA (27), Other (3), and Wallboard (7). The main area displays three gadgets:

- Crucible Charts**: By Atlassian • Local. Description: Chart Crucible review and comment data. Buttons: Show XML link, Add gadget.
- FishEye Charts**: By Atlassian • Local. Description: Chart LOC data from a FishEye repository. Buttons: Show XML link, Add gadget.
- FishEye Recent Changesets**: By Atlassian • Local. Description: Show recent changesets from a FishEye repository path. Buttons: Show XML link, Add gadget.

Depending on the gadget you selected, some gadgets will require additional options to be configured. For these gadgets, you will be presented with their configuration screen on the dashboard. Fill in the options and click on the **Save** button.

The following screenshot shows the configuration screen for the **Filter Results** gadget, where you can select the search filter to display and control the number of results to show and the fields to include. One common parameter is the **Refresh Interval** option, where you can decide how often the gadget can refresh its content or stay static if you choose **never**. Whenever you refresh the entire dashboard, all gadgets will load the latest data, but if you stay on the dashboard for an extended period of time, each gadget can automatically refresh its

data, so the content will not become stale overtime.

Take a look at the following screenshot:

Filter Results

Saved Filter:

[Advanced Search](#)

Number of Results:

Number of results to display (maximum of 50).

Columns to display

Drag-drop to reorder the fields.

Add fields to the list above by selecting them.

Auto refresh Update every 15 minutes

Moving a gadget

When you add a gadget, it's usually added to the first available spot on the dashboard. This sometimes might not be where you want to display the gadget on the dashboard, and in other cases, you might want to move the existing gadgets around from time to time. As the owner of the dashboard, you can easily move gadgets on a dashboard through a simple drag-and-drop interface:

1. Browse to the dashboard that has gadgets you wish to move.
2. Click on the gadget's title and drag it to the new position on the dashboard.

As soon as you drop the gadget to its new location (by releasing your mouse button), the gadget will be moved permanently until you decide to move it again.

Editing a gadget

After configuring your gadget when you first place it on your dashboard, the gadget will remember this and use it to render its content. You can update the configuration details or even its look and feel, as follows:

1. Browse to the dashboard that has gadgets you wish to update.
2. Hover over the gadget and click on the down arrow button at the top-right corner of it. This will bring up the gadget configuration menu.
3. Click on the **Edit** option.
4. This will change the gadget into its configuration mode.
5. Update the configuration options.
6. Click on the **Save** button to apply the changes:

The preceding screenshot shows the **Edit** menu for the **Assigned to Me** gadget. You can force a refresh with the **Refresh** option. Since gadgets retrieve their data asynchronously through AJAX, you can use this option to refresh the gadget itself without refreshing the entire page. The edit, delete, and color options are only available to the owner of the dashboard.

Deleting a gadget

As the owner of the dashboard, you can remove the existing gadgets from the dashboard when they are no longer needed. When you remove a gadget from a dashboard, please note that all the other users who have access to your dashboard will no longer see it:

1. Browse to the dashboard that has gadgets you wish to delete.
2. Hover over the gadget and click on the down arrow button at the top-right-hand corner of it. This will bring up the gadget configuration menu.
3. Click on the **Delete** option.
4. Confirm the removal when prompted.

Once removed, the gadget will disappear from the dashboard. If you choose to re-add the same gadget again at a later stage, you will have to reconfigure it again.

The HR project

In our previous chapters and exercises, we built and customized a JIRA project to collect data from users. What we need to do now is process and present this data back to the users. The goal we are trying to achieve in this exercise is to set up a dashboard for our HR team, which will have useful information such as statistics and issue listings, which can help our team members to better organize themselves to provide better services to other departments.

Setting up filters

The first step is to create a useful filter that can be shared with the other members of the team and that also acts as a source of data to feed our gadgets. We will use the advanced search to construct our search:

1. Browse to the **Issue Navigator** page.
2. Click on the **Advanced** link to switch to advanced search with JQL.
3. Type the project = HR and issuetype in ("New Employee", Termination) and resolution is empty order by priority code in the JQL search query.
4. Click on the Search button to execute the search.
5. Click on the **Save as** button to bring up the **Save Filter** dialog.
6. Name the filter **Unresolved HR Tasks** and click on the **Submit** button.
7. Share the filter with the hr-team group setup from [Chapter 9, Securing JIRA](#), by clicking on the **Details** link next to the **Save as** button.

This filter searches for and returns a list of unresolved issues of the type **New Employee** and **Termination** from our HR project. The search results are then ordered by their priority so that the users can determine the urgency. As you will see in the later steps, this filter will be used as the source of data for your gadgets to present information on your dashboard.

Setting up dashboards

The next step is to create a new dashboard for your help desk team. What you need is a dashboard specifically for your team so that you can share information easily. For example, you can have the dashboard displayed in a large overhead projector showing all the high priority incidents that need to be addressed:

1. Browse to the **Manage Dashboards** page.
2. Click on the **Create new dashboard** button.
3. Name the new dashboard **Human Resources**.
4. Select a **Blank** dashboard as your base.
5. Check the new dashboard as favorite.
6. Share the dashboard with the **hr-team** group.
7. Click on the **Add** button to create the dashboard.

In your example, we will use the two default column layouts for your new dashboard. Alternatively, you are free to experiment with other layouts and find the ones that best suit your needs.

Setting up gadgets

Now that you have set up your portal dashboard page and shared it with the other members of the team, you need to start adding some useful information to it. One example would be to have on the dashboard display all the unresolved incidents that are waiting to be processed. JIRA has an **Assigned to Me** gadget, which shows all the issues that are assigned to the currently logged-in user, but what you need is a global list irrespective of the assignee of the incident.

Luckily, JIRA also has a **Filter Results** gadget, which displays search results based on a search filter. Since you have already created a filter that returns all the unresolved incidents in your **Help Desk** project, the combination of both will nicely solve your problem:

1. Browse to the **Human Resources** dashboard you have just created.
2. Click on the **Add Gadget** option at the top-right corner.
3. Click on the **Add gadget** button for the **Filter Results** gadget.
4. Select the **Unresolved HR Tasks** filter you created.
5. Add any additional fields you wish to add for the **Columns to display** option.
6. Enable **Auto refresh** and set the interval to 15 minutes.
7. Click on the **Save** button.

This will add a new **Filter Results** gadget to your new dashboard, using your filter as the source of data. The gadget will auto-refresh its contents every 15 minutes, so you will not need to refresh the page all the time. You can add some other gadgets to the dashboard to make it more informative and useful. Some other useful gadgets include the **Activity Stream** and **Assigned to Me** gadgets.

Putting it together

This is pretty much all you have to do to set up and share a dashboard in JIRA. After you have added the gadget to it, you will be able to see it in action. The great thing about this is that since you have shared the dashboard with others on the team, they will be able to see the dashboard too. Members of the team will be able to search for your new dashboard or mark it as a favorite to add it to their list of dashboards.

You do have to keep in mind that, if you are using a filter as a source of data for your gadget, you have to share the filter with other users too, otherwise, they will not be able to see anything from the gadget.

Summary

We covered how users can search and report on the data they have put into JIRA, which is an essential component for any information system. JIRA provides a robust search facility by offering many different search options to users, including quick, simple, and advanced searches. You can save and name your searches by creating filters that can be rerun at later stages to save you from recreating the same search again.

JIRA also allows you to create configurable reports on projects or results brought back from search filters. Information can be shared with others through a dashboard, which acts as a portal for users to quickly get a glance of the data kept in JIRA.

In the next chapter, we will look at the other application in the JIRA family, JIRA Service Desk, which helps to change JIRA into a fully functional service desk with powerful features, such as the customer portal and SLA management.

Chapter 11. JIRA Service Desk

JIRA was originally designed and intended as a tool for developers. It was also designed to be an issue-tracking tool to capture bugs and tasks as they build software. However, its flexibility and extensibility allowed users to use and adapt it into almost any other use cases.

Recognizing this and JIRA's potential, a new product called JIRA Service Desk from Atlassian has been released, which was built on top of the JIRA platform, transforming it into a fully-fledged service desk solution.

By the end of the chapter, you will learn the following topics:

- Installing JIRA Service Desk
- Creating and branding a new service desk
- Defining and setting up a service-level agreement
- Creating custom queues for agents to work from
- Integrating with Confluence to set up a knowledge base

JIRA Service Desk

In each of our previous chapters, we were building JIRA as a support system, which is a part of our end of chapter exercise. While JIRA is more than capable of handling the requirements of a service desk, there are still a number of things to be desired.

For example, the user interface is often too complicated and confusing for business users to simply create a support ticket. Despite our best efforts, there are still way too many options on the screen, most of which are not useful in a Service Desk Environment. Another example is the lack of ability to set up any sort of service-level agreement to ensure a consistent quality of service.

This is where JIRA Service Desk comes in. It addresses all the out-of-the-box shortcomings of JIRA by providing a clean, intuitive, and user-friendly interface for both the end customers and support team. It also provides many features that you can expect from a service desk solution. As shown in the following screenshot, JIRA Service Desk lets you serve your customers in four easy steps:

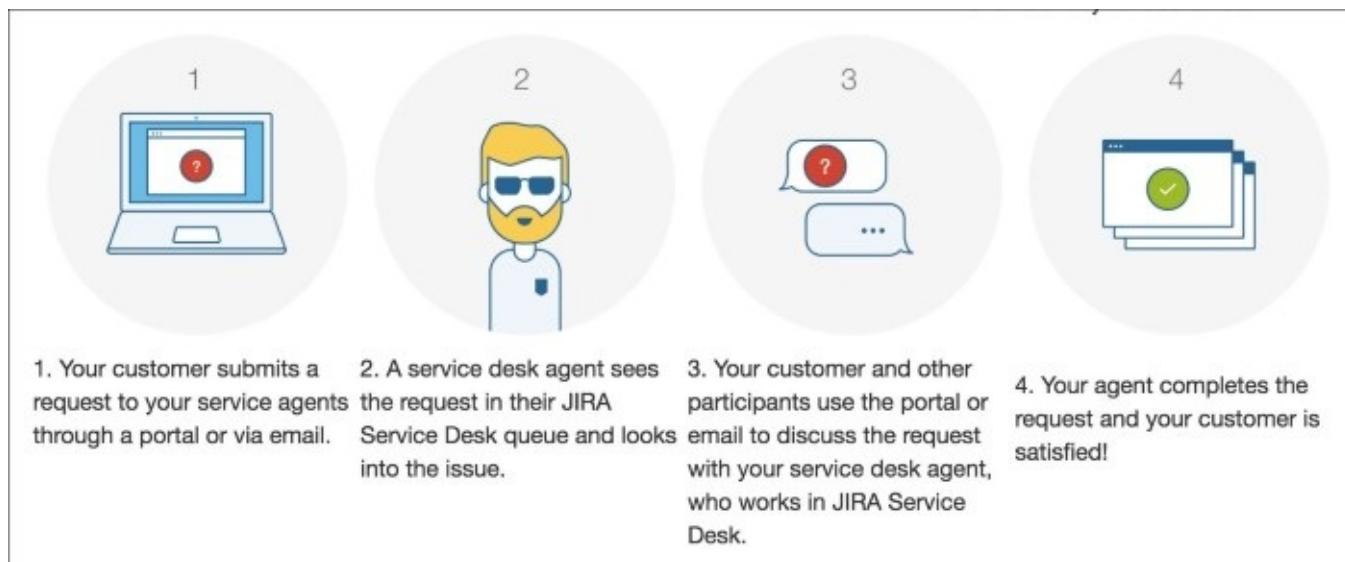

Image source:

<https://confluence.atlassian.com/display/SERVICEDESK/Getting+started+with+JIRA+Service+>

Installing JIRA Service Desk

There are two ways you can get JIRA Service Desk. The first option is to install it into an existing JIRA Core or JIRA Software you have. This is the easiest approach, as it does not require you to provision additional hardware and lets you leverage what you already have. It also makes it easy for your agents to collaborate with other teams to help resolve customer requests. These are the steps you should follow to install JIRA Service Desk:

1. Log in as a JIRA administrator user.
2. Browse to the JIRA administration console.
3. Select the **Applications** tab.
4. Click on the **Try it for free** button under JIRA Service Desk from the right panel.
5. Accept the user agreement and follow the onscreen instructions to complete the installation:

OTHER JIRA APPLICATIONS

JIRA Service Desk

Service and support for teams. Put the power of JIRA in the hands of your service desk team. JIRA Service Desk combines an intuitive, user-friendly experience with powerful SLA management and real-time reporting.

[Try it for free](#)

The second option is to install JIRA Service Desk as a standalone application. Use this option if you do not have a JIRA Core or JIRA Software instance already running, or if you would like to keep your software issue tracking system and support system separate. Your agents and other teams can still collaborate to resolve customer requests as in option one. It just takes a

few extra steps to set up. These are as follows:

1. Create an application link between the two JIRA instances.
2. Integrate both JIRA instances with the same user repository such as LDAP to ensure that you have the same set of user details in both systems.

To install JIRA Service Desk as a standalone application, you can refer to [Chapter 1, Getting Started with JIRA](#), as the installation steps are mostly identical.

Getting started with JIRA Service Desk

Before we start using JIRA Service Desk, it is important to understand that we familiarize ourselves with the key terminology, as follows:

- **Agents:** These are members of your service support team that will be working on customer requests. They are your normal JIRA users that can perform actions such as editing, assigning, and closing requests.
- **Customers:** These are the end users that will be raising support requests in your service desk. These can be customers of your product, or colleagues from other departments needing IT support.
- **Customer portal:** This is the main landing page for your customers. It is a simple, clean, and easy-to-use front interface for your service desk, without all the extra noise from the standard JIRA interface. The following screenshot shows the customer portal from Atlassian's support portal:

The screenshot shows the Atlassian Support JIRA Service Desk customer portal. The top navigation bar includes 'Atlassian Support' and 'My requests'. Below the header, there's a 'Help Center' section with the title 'JIRA Service Desk'. A welcome message says 'Welcome to JIRA Service Desk. Raise a request using one of the options below.' There's a search bar with the placeholder 'Find a solution'. Below the search bar are four categories: 'Submit a problem report to us' (warning icon), 'Need help configuring your product?' (gear icon), 'Need help installing your product?' (wrench icon), and 'Have questions about making the most of your Atlassian product suite?' (document icon). Each category has a brief description underneath.

- **Queues:** These are like JIRA filters that show you a subset of issues that meet a certain criteria. Service desk agents use queues to prioritize and pick out requests to work on.
- **Requests:** These are what your end users (not agents), such as customers, submit to JIRA Service Desk. Under the hood, they are just normal JIRA issues. However, using the term request is less confusing in the context of a service desk environment. In short, requests

are what your customers see, and issues are what agents see.

- **Service desks:** These are where customers will raise their requests. Under the hood, a service desk is a JIRA project of the **Service Desk** project type. Please refer to [Chapter 2, Using JIRA for Business Projects](#), for more information on project types.

As shown in the following screenshot, when customers interact with requests, the user interface is very different to what agents will see. It is much simpler to show only the key information, such as the request description and its status. Customers cannot make changes to the request details, and can only add new comments or attachments to the request:

The screenshot shows a JIRA Service Desk request page. At the top, it says "Help Center / IT Service Desk" and the title of the request is "Getting access denied error when accessing JIRA". The status is "WAITING FOR CUSTOMER". A comment input field says "Comment on this request...". To the right, there's a "Reference: IT-6" link and a "People involved" section showing "Sam Jones Creator" with a "+ Add people" button. Below that is a "You can" section with a "Add a comment" button. The main body of the request shows a message from "Patrick Li" at 3:55 PM asking for a screenshot of the error message. The status then changes to "Waiting for support" at 3:52 PM, and later to "Waiting for customer". The "Details" section contains a "Description" field with the text: "When accessing JIRA, I am able to log in, but after JIRA has accepted my credentials, I see an error message that says \"You do not have permission\"."

The key information of service desk is as follows:

- **Request type:** This represents the different types of requests customers can make. These can be anything including a problem report, help request, or general inquiry. When you create a new request type, JIRA creates a new issue type behind the scenes. One major feature of request type is that it allows you to specify a user-friendly name for it. While the actual issue type is called problem report, you can rename it and display it as **Submit a problem report** instead.

- **Service desk:** This is what agents will be working from. Each service desk has a front, customer-facing portal. Behind the scenes, a service desk is a JIRA project controlled by JIRA permissions, workflows, and other schemes.
- **SLA:** Service-level agreement defines the quality of service that is being guaranteed to your customers. In JIRA Service Desk, SLAs are measured in time, such as response time and overall time taken to resolve issues.

Creating a new service desk

The first step to start working with JIRA Service Desk is to set it up. Since under the hood, a service desk is a JIRA project with a brand new user interface; you can either create a new service desk from scratch, or change an existing project to be of the Service Desk project type.

To create a new service desk, perform the following steps:

1. Select the **Create project** option from the **Projects** drop-down menu.
2. Choose a project template, such as **IT Service Desk**, from the **Service Desk** project type and click on **Next**.
3. Enter the name and key for the new service desk project and click on **Submit**:

The screenshot shows the 'Create project' dialog box. At the top left is the title 'Create project'. At the top right is a link 'View Marketplace Workflows'. Below the title, there's a section for 'SERVICE DESK' containing two options: 'Basic Service Desk' and 'IT Service Desk'. 'Basic Service Desk' is described as helping the service team solve tickets faster by prioritizing, tracking, and making customers happy. 'IT Service Desk' is described as providing service management out of the box for incidents, service requests, and more. Below this, there's a 'BUSINESS' section with three options: 'Project management' (described as planning, tracking, and reporting work within a project), 'Task management' (described as quickly organizing and assigning simple tasks), and 'Process management' (described as tracking work activity through a streamlined process). At the bottom of the dialog are links for 'Import a project' and 'Create with shared configuration', and buttons for 'Next' and 'Cancel'.

If you choose to use an existing JIRA project for your service desk, all you have to do is update the project's type by following these steps:

1. Browse to the project administration page for the project you want to turn into a service desk.
2. Select the **Change project type** option from the **Actions** menu.
3. Select the **Service Desk** option and click on **Change**.

Once your service desk is created, you will be taken to your service desk user interface, as

shown in the following screenshot:

The screenshot shows the IT Service Desk interface. On the left is a navigation sidebar with icons for Queues, Customers, Reports, Customer channels, Invite team, and Welcome guide. It also includes a section for PROJECT SHORTCUTS where users can add links to useful information. At the bottom of the sidebar is a link to Give service desk feedback.

The main area is titled "All open" and shows a table of open tickets. The columns are Time to resolution, T, Key, Status, Summary, Created, Reporter, and Due. There are four visible tickets:

Time to resolution	T	Key	Status	Summary	Created	Reporter	Due
-21:28	IT-2	WAITING FOR SUPPORT	Phone system is down	04/Oct/16	Kim Lee		
-17:25	IT-5	WAITING FOR SUPPORT	Project Hummingbird team laptop upgrade	04/Oct/16	John Clark	06/Oct/16	
	IT-6	PENDING APPROVAL	FOR CUSTO... Getting access denied error when accessing JIRA	04/Oct/16	Sam Jones		

Below the ticket table is a section titled "Customer portal" with a preview URL: <http://localhost:8085/servicedesk/customer>. It also includes a "Visit the portal" link and an "Email" section with instructions on tracking customer emails.

Every service desk has two interfaces. One that will be used by you as the admin and members of your support team called **agents**. The second interface is called the **customer portal**, which is what customers will see and use to create requests and interact with agents. As you make configuration changes for your service desk, you can always preview the change by clicking on **Customer channels** and then the **Visit the portal** link from the left navigation panel, which will show you what the customer portal will look like.

Note

The URL shown under the **Customer** portal is what your customers should use to access your service desk.

Branding your customer portal

You can brand your customer portal for your service desk with the following options:

- **Help center name:** This is the overall name for your help center. Think of this as the name for your JIRA instance.
- **Help center logo:** This is the logo for your help center that will appear in the top-left corner. Think of this as the logo for your JIRA. JIRA Service Desk will use this logo to automatically change and adjust the top bar color.
- **Customer portal name:** This is the name for a specific service desk portal.
- **Customer portal introduction text:** This is a welcome text that will be displayed for a specific service desk portal.
- **Customer portal logo:** This is the logo for a specific service desk portal.

The following screenshot illustrates each of these items on a sample customer portal:

The screenshot shows a JIRA Service Desk interface with the following branding elements:

- Global Service Center** (top left)
- Requests** (top right)
- Profile icon** (top right)
- Header:** Trial launch of our new IT Service Desk
- Image:** Megaphone icon
- Description:** This is our soft launch of our new IT Service Desk. You should raise your new IT requests here. The old service desk is placed under read-only mode, and you can access it [here](#).
- Feedback:** Please let us know what you think of this new service desk at it-feedback@company.com.
- Section:** Global Service Center
- Title:** IT Service Desk
- Welcome message:** Welcome! You can raise a IT Service Desk request from the options provided.
- Common Requests:** A list of five categories with icons:
 - 1. Common Requests (Question mark icon)
 - 2. Logins and Accounts
 - 3. Computers (Computer monitor icon)
 - 4. Applications
 - 5. Servers and Infrastructure
- Get IT help:** Get assistance for general IT problems and questions.
- Desktop/Laptop support:** If you are having computer problems, let us know [here](#).
- Request new software:** If you need a software license, raise a request [here](#).
- Request new hardware:** For example, a new mouse or monitor.

To configure a specific customer portal's branding, perform the following steps:

1. Browse to the project administration page of the service desk you want to brand.
2. Select **Portal settings** from the left panel.
3. Enter a name and welcome text in **Name** and **Introduction text** fields respectively.
4. Check the **Use a custom logo for this Customer Portal** option and upload a logo for

your customer portal:

Portal settings

Title

Name

Trial launch of our new IT Service Desk

Message

This is our soft launch of our new IT Service Desk. You should raise your new IT requests here. The old service desk is placed under read-only mode, and you can access it [here](#).

Please let us know what you think of this new service desk at it-feedback@company.com.

Links: [link name]<http://example.com>

Service desk users

JIRA Service Desk introduces a number of new user types. Under the hood, these user types are mapped to the following new project roles created by the JIRA Service Desk when it is installed:

- **Agent:** These are members of the service desk team that work on requests. Agents are added to the **Service Desk Team** project role.
- **Customer:** These are end users that will be submitting requests through your help desk portal. Customers are added to the **Service Desk Customers** project role.
- **Collaborator:** These are the other JIRA users that are not usually members of your service desk team, but can help solve customer problems. Collaborators are added to the **Service Desk Team** project role.

Adding an agent to service desk

Agents are JIRA users that will be working on customer requests in JIRA Service Desk. These are usually members of your support team. Agents consume the JIRA Service Desk licenses. To add an agent to a service desk, do the following:

1. Browse to the service desk you want to add an agent to.
2. Click on the **Invite team** option on the left panel.
3. Search and add users you want to invite as an agent (member) of your service desk team. You can select and add more than one agent. Click on the **Invite** button:

The screenshot shows the JIRA Service Desk interface. On the left, there's a sidebar with options: 'Customer channels', 'Invite team' (which is selected and highlighted in blue), and 'Welcome guide'. Below that is a 'PROJECT SHORTCUTS' section with a link to 'Add a link'. At the bottom is a 'Give service desk feedback' link. On the right, a modal window titled 'Invite team' is open. It contains the text 'Add people as agents to work on your project. They will be sent an email invite.' Below this is a search bar with the name 'sam' typed in. A list of users is shown, with 'Sam Jones - sam@test.com (sam)' selected. Below the list are four user icons: a man with sunglasses, a woman in a superhero costume, an older man with a beard, and a man with a yellow beard. At the bottom of the modal are two buttons: 'Invite' (highlighted in blue) and 'Cancel'.

When adding an agent to a service desk, you can select an existing user in JIRA, which will grant the user access to the service desk. If the user you want to add as an agent does not exist, you can also create a new JIRA account and add him/her as an agent in one step by typing in the user's e-mail address. An e-mail will be sent out with a link to set his/her password. New user accounts created this way will be automatically added to the **jira-servicedesk-users** group and **Service Desk Team** project role. Refer to [Chapter 9, Securing JIRA](#), for more information on groups and roles.

Adding a customer to service desk

Customers are end users that will be creating requests through your customer portal. You can manually invite customers or allow them to sign up themselves. JIRA Service Desk requires customers to have an account to submit requests. The good news is that customers do not consume the JIRA Service Desk licenses. To invite a customer to a service desk, perform the following steps:

1. Browse to the service desk you want to add a customer.
2. Select the **Customers** option from the left panel.
3. Click on the **Invite customers** button.
4. Enter the e-mail addresses of customers to invite and click on the **Send invites** button.

E-mails will be sent out to customers with details on how to access the customer portal and steps to create an account if necessary.

If you want to allow users to sign up themselves, you will need to set your service desk to **Everyone can access** and enable the **Anyone can sign up** option, as shown in the following screenshot. If you want to restrict your service desk to only a list of pre-approved customers, then you will need to select the **Only people on my customer list can access my Customer Portal** option:

The screenshot shows the 'Customers' page in JIRA Service Desk. On the left, there's a table listing four customers: John Clark, Kim Lee, Patrick Li (AGENT), and Sam Jones (AGENT). Each row shows the customer's name, email address, and their status (0 open, 1 closed). Above the table is a search bar with placeholder text 'Find customers by name or email'. To the right of the table, a modal window titled 'Invite customers' is open. It contains a text input field with the value 'tom@test.com' and a note below it saying 'Enter one or more emails to invite'. At the bottom of the modal are two buttons: 'Send invites' and 'Cancel'.

Customer	Email	0 open	1 closed
John Clark	john@test.com		
Kim Lee	kim@test.com		
Patrick Li <small>AGENT</small>	patrick@appfusions.com		
Sam Jones <small>AGENT</small>	sam@test.com	1 open	0 closed

Adding a collaborator to service desk

Collaborators are JIRA users that are not part of your support team (not agents), but have expert knowledge and understanding in the domain area that can assist agents to diagnose and solve customer requests. In JIRA Service Desk, collaborators are users in the **Service Desk Team** project role but not in the **jira-servicedesk-users** group, and adding a user as a collaborator is an easy way to grant that user access to your service desk project. Collaborators do not consume JIRA Service Desk licenses.

To add a collaborator to your service desk, following these steps:

1. Browse to the project administrator page for the service desk you want to add a collaborator to.
2. Select the **Users and roles** option from the left panel.
3. Click on the **Add users to a role** link.
4. Search and select the users to add, choose the **Service Desk Team** role, and click on the **Add** button.

When making a user a collaborator, you are simply granting permission for the user access to your service desk, so he/she can view, comment, and add attachments to the request.

Request types

JIRA uses issue types to define the purpose of issues, while the JIRA Service Desk uses request types for the same purpose. In fact, each request type is mapped to an issue type behind the scenes. The one key difference between the two is that a request type is what is shown to the customers, and a more descriptive display name is used. For example, an issue type is called **Incident**, and the corresponding request type will be called **Report system outage**. You can think of request types as issue types with a more informative display name.

Setting up request types

To create a new request type for your service desk, do the following:

1. Browse to the project administration page for the service desk that you want to create a new request type for.
2. Select the **Request Types** option from the left panel.
3. Click on the icon to select a new icon for the request type.
4. Enter a name for the request type. You can be as descriptive as possible with its name, so your customers can easily understand its purpose.
5. Select the issue type that the request type is mapped to.
6. Enter an optional description. The description will be displayed underneath the request name to help your customer decide what type of request to create.
7. Select a group or groups this request type belongs to. We will talk about groups later in this section.
8. Click on the **Add** button to create the new request type:

Request types					
Icon	Request name	Issue type	Description (Optional)	Groups	Actions
	Request new hardware	Service Request		Hardware	<button>Add</button>
	Report a system problem	Incident	Having trouble with a system?	<ul style="list-style-type: none">1. Common Requests4. Applications5. Servers and Infrastructure	<button>Edit fields</button> <button>Delete</button>
	Get IT help	Service Request	Get assistance for general IT problems and questions.	<ul style="list-style-type: none">3. Computers1. Common Requests	<button>Edit fields</button> <button>Delete</button>

You can reorder the request types by dragging them up and down the list. The order you set in the list will be reflected on the customer portal. Make sure you put some thought into this. For example, you can order them alphabetically or by placing the most common request types at the top.

Organizing request types into groups

As the number of request types grows, you can group similar request types into groups. Therefore, when customers visit the portal, all the request types will be organized logically, making navigation much easier. For example, as shown in the following screenshot of a customer portal, we have six request type groups, where the first five come with JIRA Service Desk's project templates, and there's a custom sixth, **Sample Group**. When clicking on **Sample Group**, we have the three request types that customers can raise:

The screenshot shows the 'IT Service Desk' interface. At the top left is a logo of a person at a desk with a computer. To its right is the text 'Global Service Center' and 'IT Service Desk'. Below this is a welcome message: 'Welcome! You can raise a IT Service Desk request from the options provided.' On the left, a vertical list of request type groups is shown: 1. Common Requests, 2. Logins and Accounts, 3. Computers, 4. Applications, 5. Servers and Infrastructure, and 6. Sample Group. To the right of this list, three specific request types are detailed with icons: 'Sample Change' (refresh icon), 'Sample Incident' (lightning bolt icon), and 'Sample Request' (plus sign icon). Each entry includes a brief description of the request type.

Request Type Group	Description
1. Common Requests	Request change to an existing IT system, such as upgrade.
2. Logins and Accounts	Report a problem or incident encountered with IT systems.
3. Computers	Request assistance from IT team.
4. Applications	
5. Servers and Infrastructure	
6. Sample Group	

As we have already seen in the *Setting up request types* section, you can add one or more groups to a request type. You can select one of the existing groups or create a new group by simply typing in the new group's name. When a request type belongs to two or more groups, it will be displayed when each of the group is selected on the portal.

Tip

You cannot reorder request type groups. One way to get around this is by adding a number in front of the group name, for example, 1 General and 2 Application Update.

Setting up fields

JIRA Service Desk lets you set up different field layouts for each request type. The important thing to note here is that, when you are setting up fields for JIRA Service Desk, you are not creating new custom fields (as you would in JIRA Software), you are simply adding and removing existing fields in the request form when customers create a new request. You can think of this as adding fields onto screens. If you want to add a field that does not yet exist, you will have to create a new custom field first, as described in [Chapter 5, Field Management](#), and then make it available in the request form.

Just like with request types, JIRA Service Desk allows you to give a custom display name to the field, independent of the actual field's name. This means that the field can be more informative when displayed to customers. For example, for the JIRA field **Summary**, you can give it a display name of **What is the problem you are having?**. As the display name is independent of the field's name, your existing filters and search queries will continue to work as they are.

To set up field layouts for a request type, follow these steps:

1. Browse to the project administration page for the service desk you want to set up field layouts for.
2. Select the **Request Types** option from the left panel.
3. Click on the **Edit fields** link for the request type you want to set up fields for. This will list all the fields that are currently displayed when customers create a new request:

[Fields](#) [Workflow Statuses](#)This request form is linked to the following issue type: **Change** (6 of 9 field/s used)[+ Add a field](#)**Help and instructions (Optional)**[Click here for our priority policy.](#)

Links [link name|http://example.com]

Visible fields

Display name	Required	Field help (Optional)	Actions
Summary	Yes	Quick one line description of the change required	Update Cancel
Issue field: Summary			Hide Remove
When does this need to be done?	Yes		Hide Remove
What system requires the change?	Yes		Hide Remove
Priority	Yes		Hide Remove
Anything else you need to tell us?	No		Hide Remove

Hidden fields with preset values

Name	Preset value	Actions
Labels	Edit value	Show Remove

4. Click on the **Add a field** button and select an existing field (both system and custom) to add to the request type.
5. Click on the field's **Display name** to change what customers will see when the field is displayed. This does not change the field's actual name in JIRA, it only makes the display more user friendly.
6. Change the field's mandatory requirement by clicking on the **Required** column. Note that you cannot change this value if it is grayed out, such as the **Summary** field.

After you have set up your field layout for the request type, you can click on the **View this request form** link at the top to see a preview of the result. As shown in the following screenshot, we added the **Due Date** field to the form, but it is now displayed as **When does this need to be done?**:

Summary

Quick one line description of the change required

When does this need to be done?

What system requires the change?

Priority

Anything else you need to tell us? *(optional)*

Create

Cancel

Setting up workflow

Just like with fields, you can also control how workflow statuses are displayed in JIRA Service Desk. Note that you cannot actually change the actual workflow, but you can make the workflow less confusing to your customers so they know exactly how their requests are progressing.

To set up the workflow for a request type, perform the following steps:

1. Browse to the project administration page for the service desk you want to set up a workflow for.
2. Select the **Request Types** option from the left panel.
3. Click on the **Edit fields** link for the request type you want to set up a workflow for.
4. Select the **Workflow Status** tab. This will list all the workflow statuses that are available in the workflow, as shown in the following screenshot:

The screenshot shows the 'Request types / Task - Detailed' page in JIRA. At the top, there are tabs for 'Fields' and 'Workflow Statuses'. The 'Workflow Statuses' tab is selected. Below the tabs, the title 'Workflow status in JIRA' is followed by a 'view workflow' link. To the right, the title 'Status name to show customer' is listed. A table lists five workflow statuses with their corresponding display names:

Workflow status in JIRA	Status name to show customer
Open	Submitted
In Progress	Under investigation
Resolved	Completed
Reopened	Reopened
Closed	Closed

At the bottom left are 'Save' and 'Discard unsaved changes' buttons.

As we can see in the preceding screenshot, the actual JIRA workflow status names are listed in the left column. For each of the statuses, you can choose to give it a different display name that will be shown to the customers.

For example, the **Open**, **In Progress**, and **Reopened** statuses are normal JIRA workflow terms, and represent that the request is currently with a support agent. However, these names can be confusing to customers, so we give them new display names.

Note

You are not changing the workflow itself; you are simply making it more user friendly to your customers.

Service-level agreement

Service-level agreement or **SLA** defines the agreement between the service provider and end user in terms of aspects of the service provided, such as its scope, quality, or turn-around time.

In the context of support service, an SLA will define different response times for different types of support requests. For example, severity 1 requests will have a response time of 1 hour, and severity 2 requests will have a response time of 4 hours.

JIRA Service Desk lets you define SLA requirements based on response time. You can set up the rules on how response time will be measured, and goals for each rule.

Setting up SLA

JIRA Service Desk's SLA is divided into two components, the time measurement and goals to achieve. Time can be measured for a variety of purposes. Common examples include overall time taken for request resolution and response time to customer requests. To set up SLA metric, follow these steps:

1. Browse to the project administration page for the service desk you want to set up the SLA on.
2. Select the **SLAs** option from the left panel and then click on the **New Metric** button.

A simple example will be JIRA Service Desk starting to count time as soon as the request is created. Every time an agent requests for more information from the customer, the count will be paused until the customer responds back. Once the request is finally closed off, the count will be stopped. The following points shows you how to set up an SLA time measurement for the simple example:

- For the **Start** column, we will select the **Issue Created** option, indicating that it can start counting time as soon as the request is created
- For the **Pause on** column, we will select the **Status: Waiting for Info** option, indicating that the counting can be paused when the request enters the **Waiting for Info** status
- For the **Stop** column, we will select the **Entered Status: Closed** option, indicating that the counting will be stopped once the request is closed

As you can see in the following screenshot, for each of the three columns, you can select more than one condition:

Time will be measured between the **Start** and **Stop** conditions below.

Start	Pause on	Stop
Begin counting time when	Time is not counted during	Finish counting time when
<input checked="" type="checkbox"/> Issue Created <input type="checkbox"/> Assignee: From Unassigned <input type="checkbox"/> Assignee: To Unassigned <input type="checkbox"/> Assignee: Changed <input type="checkbox"/> Entered Status: Open <input type="checkbox"/> Entered Status: Resolved <input type="checkbox"/> Entered Status: Closed <input type="checkbox"/> Entered Status: In Progress <input type="checkbox"/> Entered Status: Waiting for Info	<input type="checkbox"/> Assignee: Not Set <input type="checkbox"/> Status: Open <input type="checkbox"/> Status: Resolved <input type="checkbox"/> Status: Closed <input type="checkbox"/> Status: In Progress <input checked="" type="checkbox"/> Status: Waiting for Info <input type="checkbox"/> Status: Reopened <input type="checkbox"/> Resolution: Set <input type="checkbox"/> Resolution: Not Set	<input type="checkbox"/> Assignee: To Unassigned <input type="checkbox"/> Assignee: Changed <input type="checkbox"/> Entered Status: Open <input type="checkbox"/> Entered Status: Resolved <input checked="" type="checkbox"/> Entered Status: Closed <input type="checkbox"/> Entered Status: In Progress <input type="checkbox"/> Entered Status: Waiting for Info <input type="checkbox"/> Entered Status: Reopened

This allows you to set up multiple entry points to start and stop time. An example of this usage will be to measure response time. For example, you will need to guarantee that an agent will respond to a new request within an hour. If the request is sent back to the customer for further information, a response time of one hour is also required as soon as the customer updates the request with the requested information. The following points shows you how to set up the time measurement for this SLA:

- For the **Start** column, we will select both the **Issue Create** option and **Entered Status: In Progress** option. Therefore, we will start counting when the issue is first created, and also when it is put back for our agents to work on.
- For the **Stop** column, we will select both the **Entered Status: Waiting for Info** and **Entered Status: Closed** option. Counting will stop when an agent sends the request back to the customer for more information or when it is closed for completion.

The difference between the two examples here is that, in the second example, we do not pause time counting when the request enters the **Waiting for Info** status; instead, we stop counting completely. This means that when the request enters the **Waiting for Info** status, the current counting cycle ends, and when the request enters the **In Progress** status, a new counting cycle will begin, as shown in the following screenshot:

Time will be measured between the **Start** and **Stop** conditions below.

Start	→	Pause on	→	Stop
Begin counting time when		Time is not counted during		Finish counting time when
<input type="checkbox"/> Issue Created <input type="checkbox"/> Assignee: From Unassigned <input type="checkbox"/> Assignee: To Unassigned <input type="checkbox"/> Assignee: Changed <input type="checkbox"/> Entered Status: Open <input type="checkbox"/> Entered Status: Resolved <input type="checkbox"/> Entered Status: Closed <input checked="" type="checkbox"/> Entered Status: In Progress <input type="checkbox"/> Entered Status: Waiting for Info	<input type="checkbox"/> Assignee: Set <input type="checkbox"/> Assignee: Not Set <input type="checkbox"/> Status: Open <input type="checkbox"/> Status: Resolved <input type="checkbox"/> Status: Closed <input type="checkbox"/> Status: In Progress <input type="checkbox"/> Status: Waiting for Info <input type="checkbox"/> Status: Reopened <input type="checkbox"/> Resolution: Set	<input type="checkbox"/> Assignee: To Unassigned <input type="checkbox"/> Assignee: Changed <input type="checkbox"/> Entered Status: Open <input type="checkbox"/> Entered Status: Resolved <input checked="" type="checkbox"/> Entered Status: Closed <input type="checkbox"/> Entered Status: In Progress <input checked="" type="checkbox"/> Entered Status: Waiting for Info <input type="checkbox"/> Entered Status: Reopened		

Once we have defined how time should be measured, the next step is to set up the SLA goals. The SLA goals define the amount of time allowed for each of the scenarios we have just set up. If we take the aforementioned response time example, we may set up our goals as shown in the following screenshot:

Goals

Issues will be checked against this list, top to bottom, and assigned a time target based on the first matching JQL statement.

Issues (JQL)	Goal	Calendar	
<input type="text"/>	<input type="text"/> (e.g. 4h 30m)	24/7 Calendar (Default)	
priority = Highest	1h	24/7 Calendar (Default)	
priority = High	4h	24/7 Calendar (Default)	
priority = Medium	8h	24/7 Calendar (Default)	
All remaining issues	12h	24/7 Calendar (Default)	

In our example, we defined that for requests with priority set to **Highest**, the response time will be 1 hour (**1h**); **High** requests and **Medium** requests will have a response time of 4 and 8 hours, respectively. Everything else will be responded to within 12 hours.

As you can see, there are several components when it comes to define an SLA goal, which are as follows:

- **Issues:** These will have the goal applied to them. Use JQL to narrow down the selection of issues.
- **Goal:** This is the time value for the goal. You can use the standard JIRA time notation here, where 3h means 3 hours, 45m means 45 minutes, and 2h30m means 2 hours and 30 minutes.
- **Calendar:** These define the working days and hours SLA will be applied to. For example, **24/7 Calendar** means that time will be counted every hour of every day. As we will see later, you can create your own custom calendars to define your working day, hours, and even holidays.

When defining SAL criteria, we will need to use JQL. Just like doing advanced search, JIRA Service Desk provides syntax autocomplete to help us validate our queries, as shown in the following screenshot:

Goals

Issues will be checked against this list, top to bottom, and assigned a time target based on the first matching JQL statement.

Issues (JQL)	Goal	Calendar	
<input checked="" type="checkbox"/> priority = ?	<input type="text"/> (e.g. 4h 30m)	24/7 Calendar (Default) ▼	Add
High	Syntax Help		
Highest	1h	24/7 Calendar (Default)	Delete
Low	4h	24/7 Calendar (Default)	Delete
Lowest	8h	24/7 Calendar (Default)	Delete
Medium			
All remaining issues	12h	24/7 Calendar (Default)	

Setting up custom calendars

As we have seen, when setting up SLA, you can select a calendar that defines the working days and hours, which can be counted toward the goal. JIRA Service Desk comes with a **Sample 9-5 Calendar** out of the box, which will only count the time between 9 AM to 5 PM, from Monday to Friday.

You can create your own calendars as follows:

1. Browse to the project administration page for the service desk you want to add a calendar for.
2. Select on the **SLAs** option from the left panel.
3. Click on the **Calendar** button, and then click on the **Add Calendar** button from the dialog box.
4. Enter a name for the new calendar and configure the options.
5. Click the **Save** button to create the calendar.

JIRA Service Desk lets you configure your calendar with the following options:

- **Time zone:** This selects the time zone that will be used for the calendar
- **Working days:** This select the days that can be counted toward the SLA
- **Working hours:** These are the hours of each working day that can be included in SLA
- **Holidays:** This adds holidays such as Christmas to be excluded from the SLA

As shown in the following screenshot, we have set up our calendar to have working time between 9A.M. to 5P.M., from Tuesday to Friday; this means Monday, Saturday, and Sunday are excluded when calculating SLA metrics. We also added **Christmas Day** and **New Year Day** as holidays, so the SLA will not be applied on those days:

Queues

Queues are lists of requests with predefined criteria for agents to work through. You can think of them as JIRA filters. They help you and your teams organize the incoming requests into more manageable groups, so you can better prioritize them. JIRA Service Desk uses JIRA's search mechanism to configure queues. Refer to [Chapter 10, Searching, Reporting, and Analysis](#), for more details on JIRA search options.

Creating a new queue

You, as the service desk administrator, can create new queues for your team. To create a new queue, follow these steps:

1. Browse to the service desk you want to add a queue for.
2. Select the **Queues** option from the left pane and click the **New queue** button.
3. Enter a name for the queue. It should clearly reflect its purpose and types of requests that will be in it.
4. Use the UI controls to create the search criteria. If you are familiar with JQL, or need to use exclusion logics in your query, you can click on the **Advanced** link and use JQL directly.
5. Select the fields that will be displayed when the queue is showing the issue list. Click on the **More** option to find more fields to add. You can also drag the fields left and right to rearrange them. You can select the fields that will display the most useful information.
6. Click on the **Save** button to create the queue, as shown in the following screenshot:

New queue

As shown in the preceding screenshot, when you make changes to your search criteria and field selection, there is a preview area at the bottom that will show you the result of your search and the field layout.

Creating knowledge base articles

As your team works diligently to solve problems for your customers, nuggets of knowledge will start to accumulate over time. These include things such as common questions customers face and the steps to troubleshoot them. JIRA Service Desk allows you to extract this information and create a knowledge base, which helps customers find solutions themselves. Out of the box, JIRA Service Desk only supports Atlassian Confluence for knowledge-base creation, but it is possible to use other tools via third-party add-ons.

To integrate JIRA Service Desk with Confluence, you will first have to create an **application link** between JIRA and Confluence. If you have already done this, feel free to skip to the next section. To create an application link for Confluence, perform the following steps:

1. Browse to the JIRA administration console.
2. Select the **Applications** tab and the **Application links** option from the left panel.
3. Enter the fully qualified URL to your Confluence instance in the **Application** text box and click the **Create new link** button, as shown in the following screenshot:

Configure Application Links ⓘ

LABS Try out our new Application Links page for improved status and diagnostics!

You have no application links right now. To create an application link begin by entering the URL of application you wish to link to.

Application

Create new link

4. Follow the onscreen wizard to complete the linking process.

Once the application link is created between JIRA and Confluence, we can use it for JIRA Service Desk. Each service desk will need to be individually integrated with a Confluence space. To set up a Confluence KB for a service desk, follow these steps:

1. Browse to the project administration page of the service desk you want to set up a Confluence knowledge base for.
2. Select the **Knowledge base** option from the left panel.
3. Check the **Link to a Confluence space** option.
4. Select the linked Confluence (it may be named as something other than Confluence) from the **Application** dropdown.
5. Select the Confluence space that the knowledge-base article will be created in. If you do not have a space already, click on the **Create a knowledge base space** link.
6. Click on the **Link** button to complete the integration setup, as shown in the following screenshot:

Knowledge base

Use a linked Confluence space to provide customers with knowledge base articles they can use to help themselves.

Link a Confluence space

- Don't link to a Confluence space
- Link to a Confluence space

Application

Select the Confluence application you would like to use to link a Confluence space.

Confluence

Space

You can only select spaces you have the permission to view in Confluence.

Knowledgebase

[Create a knowledge base space](#)

[Link](#)

[Cancel](#)

Note

You can link one service desk to one Confluence space.

After the integration is in place, when an agent views a request, there will be a new **Create KB article** option available. Clicking on that will allow the agent to create a new knowledge-base article in the preconfigured Confluence space, as shown in the following screenshot:

SLAs

40:00 ||

40:00 ||

People

Assignee:

Reporter:

Request participants: None

Votes: 0

Watchers: 1 Stop watching this issue

Create KB article **Export**

Primary problem / desired outcome
Install VPN client on Mac OSX

Labels

Template
How-To

Create **Cancel**

This screenshot shows a service desk interface with a modal window for creating a knowledge base article. The modal contains fields for the primary problem (Install VPN client on Mac OSX), labels, template (How-To), and assignee. It also displays reporter information, request participants (None), and a vote count of 0. A 'Watchers' section shows 1 user watching the issue. At the bottom, there are 'Create' and 'Cancel' buttons.

From the customer's perspective, a new search box will be available on the customer portal (for service desk, with the KB feature enabled). Customers will be able to search to see whether there is any information already available on their problems. As shown in the following screenshot, when searching for VPN, the service desk returns a knowledge article from past requests, and if this is what the customer is looking for, it will save valuable time for both the customer and the agent:

Process automation

When running a service desk, there are many mundane and repetitive tasks that can end up wasting a lot of your team's time. For example, after a request is closed, if the customer adds a comment afterwards, the request needs to be reopened so it will be placed back into the queue for agents to work on again. Normally, this would require either an agent to manually reopen the request, or you, as the JIRA administrator, to configure the workflow used by your service desk project to automatically reopen the request. This can be tedious for the agents, and overwhelming for you, if there are many service desk projects needing this kind of automation.

The good news is, JIRA Service Desk has a process automation feature that greatly reduces the complexity and allows each service desk owner (users with **Administer Projects** permission) to set up the automation rules, as shown in the following screenshot:

The screenshot shows the 'Automation' page in JIRA Service Desk. At the top left is the title 'Automation'. To its right is a dropdown menu set to 'Oldest first'. On the far right is a button labeled 'Add rule'. Below this is a table listing two automation rules:

Transition on comment	Run as project default (Automation User)	Edit	Delete
Issue commented			
Assign to agent on customer comment	Run as project default (Automation User)	Edit	Delete
Issue commented			

To the right of the table is a sidebar with the following text and buttons:

- All automation rules are run as a specific user. Any comments or edits will show as being made by this user.
- You can set an individual rule to run as the user who triggered the rule, e.g. transition an issue 'as the customer' in response to a customer comment.
- Set the default user for this project's automation rules below.

A large 'Run as Automation User' button is at the bottom of the sidebar.

Follow the steps below to set up automation rules:

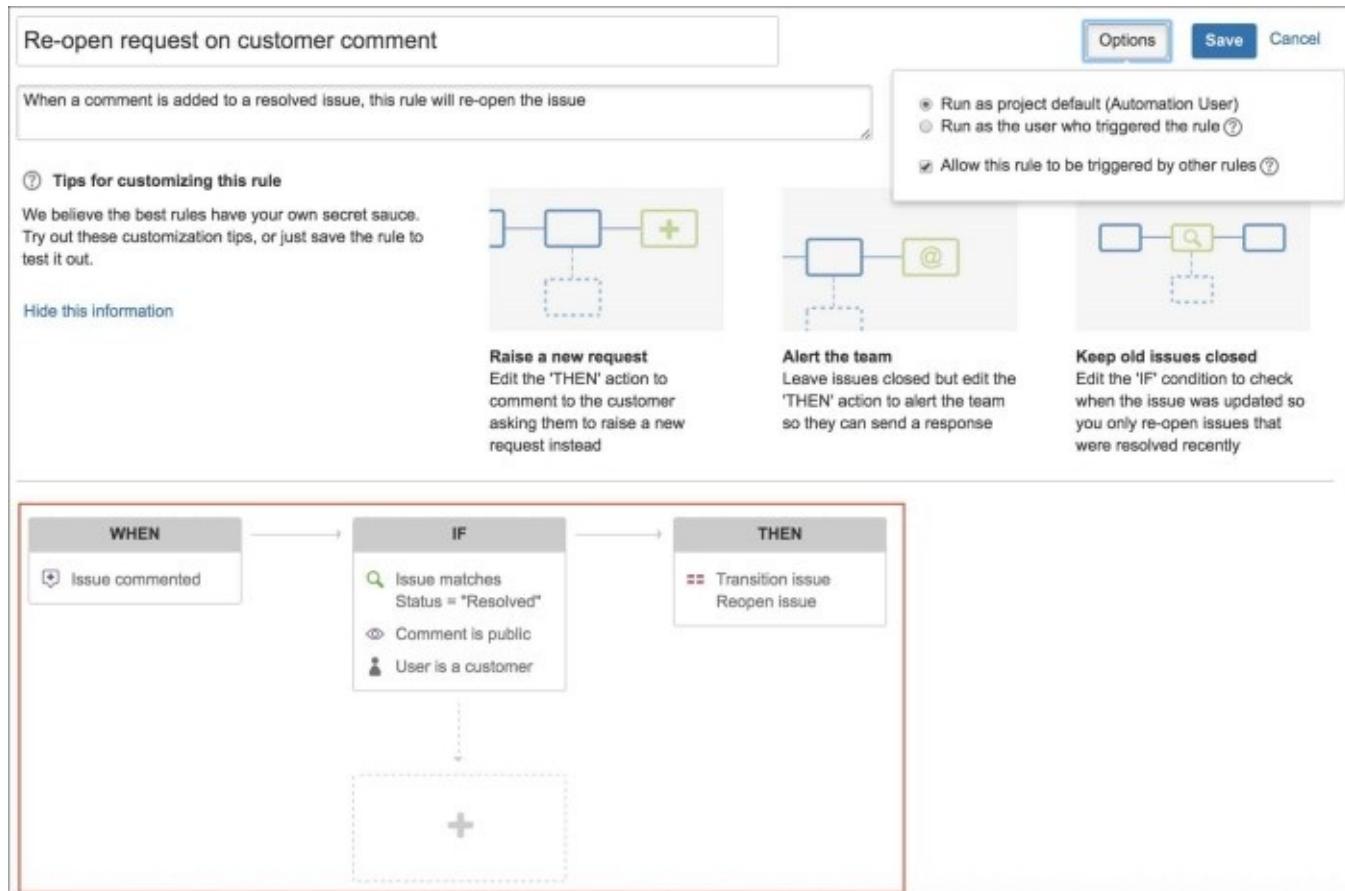

1. Browse to the project administration page of the service desk you want to set up automation rules for.
2. Select the **Automation** option from the left panel.
3. Click on the **Add rule** button to create a new automation rule.
4. Select from one of the pre-made automation rule template from the dialog box, or select the **Custom rule** option from the button to create one from scratch.
5. Enter a name for the new automation rule.
6. Configure the automation rule and click **Save**.

There are a number of things to consider when configuring your automation rule. Firstly, each rule is made up of three parts called **WHEN**, **IF**, and **THEN**, as shown in the next screenshot. The way to think about this is that your rule should read something like this: **when**

something happens on a request, if the criterion is met, then execute the following actions. So, if we take the customer adding comment to a closed request example, the rule may be something like this: **when a comment is added, if the request is in Closed status, then transition the request to Re-opened.**

You configure these components of the automation rule by clicking on the UI elements representing each component. There are a few points to keep in mind when designing your rule:

- You can only have one **WHEN**, which acts as the entry point for the rule. However, it can have multiple triggers, so each rule can be triggered by more than one action.
- You can have more than one **IF** (as **ELSE IF**), so you can set up multiple criteria to evaluate when the rule is triggered.
- You can have only one **THEN**, which can have multiple actions to execute, as shown in the following screenshot:

Other options include the following:

- Whether the rule should be run as the user who triggered it or a dedicated user set for the service desk project. As not all actions can be run as the user who triggers it, especially if the user is a customer, it is safer to use the project default option.
- Whether the rule can be triggered by another automation rule. This is very useful as it

allows you to chain multiple rules together to automate your process. However, you need to be careful and make sure you do not have rules that will trigger off each other and get stuck in a loop.

Summary

In this chapter, you learned how to use JIRA Service Desk to transform JIRA into a powerful service desk solution. The JIRA Service Desk is built based on many of JIRA's out-of-the-box features, such as workflow engine and search query (JQL), and provides a brand new user interface to remove the friction caused by the old JIRA interface. This makes the overall experience a lot more pleasant for the customers.

This is the last chapter and the end of our journey. Throughout this book, we looked at the various offerings in the JIRA 7 product family and how they can be used to bring value to your organization. Whether you need a project management tool to run agile projects, a service desk solution to support your customers, or simply a tool to better manage and track tasks, JIRA 7 has it covered.

We also looked at how you, as an administrator, can install, morph, and adapt it to your environment and use cases. Features such as custom fields and workflows make JIRA a very flexible solution that can adapt to your requirements. These features can be further extended by third-party add-ons; we have introduced several popular ones that can bring more capabilities to JIRA, and they are just a few out of thousands more available. Now, it is your job to discover and try other add-ons to enhance you and your users' experience using JIRA, and to make it a success.
